What does the compiler actually do with my code?

An introduction to the C++ ABI

Filip Strömbäck

LINKÖPING
UNIVERSITY

The topic for today

How are parts of C++ realized on x86 and AMD64?

- Object layout
- Function calls
- Virtual function calls
- Exceptions

Why?

If you know the implementation...

- ...you can reason about the efficiency of your solution
- ...you can see why some things are undefined behaviour
- (...you can abuse undefined behaviour and do *really* strange things)

Note: Everything discussed here is *highly* system specific, and most likely undefined behavior according to the standard!

IN.U LINKÖPING

How?

- Read the assembler output from the compiler!
  - g++ -S <file> or cl /FAs <file>
  - objdump -d <program>
  - In a debugger
  - Compiler Explorer
- Figure out why it does certain things:
  - OSDev Wiki (https://wiki.osdev.org/)
  - System V ABI (https://www.uclibc.org/docs/psABI-x86_64.pdf)
  - x86 instruction reference (http://ref.x86asm.net/)
- Lots of tinkering and thinking!

LiU LINKÖPING
UNIVERSITY

LINKÖPING
UNIVERSITY

What is an ABI (Application Binary Interface)?

Specifies how certain aspects of a language are realized on a particular CPU

Language specification $+$ ABI $\Rightarrow$ compiler

Specifies:

- Size of built-in types
- **Object layout**
- **Function calls** (calling conventions)
- Exception handling
- Name mangling
- ...

I.U LINKÖPING
UNIVERSITY

Different systems use different ABIs

There are two major ABIs:

- System V ABI (Linux, MacOS on AMD64)
- Microsoft ABI (Windows)

Variants for many systems:

- **x86**
- **AMD64**
- ARM
- ...

UNIVERSITY

Memory

Memory

Memory

LINKÖPING
UNIVERSITY

Integer types and endianness

```
char  a{0x08};
short b{0x1234};        // = 4660
int   c{0x00010203};    // = 66051
long  d{0x1101020304};  // = 73031353092
```

Integer types and endianness

```
char  a{0x08};
short b{0x1234};        // = 4660
int   c{0x00010203};    // = 66051
long  d{0x1101020304};  // = 73031353092
```

Big endian (ARM)

a: | 08 |

b: | 12 | 34 |

c: | 00 | 01 | 02 | 03 |

d: | 00 | 00 | 00 | 11 | 01 | 02 | 03 | 04 |
Integer types and endianness

```
char  a{0x08};
short b{0x1234};        // = 4660
int   c{0x00010203};    // = 66051
long  d{0x1101020304};  // = 73031353092
```

Little endian (x86)

a: | 08 |

b: | 34 | 12 |

c: | 03 | 02 | 01 | 00 |

d: | 04 | 03 | 02 | 01 | 11 | 00 | 00 | 00 |

The type system

The type system is not present in the binary! It just helps us to keep track of how to *interpret* bytes in memory!

```
struct foo {
  int a, b, c;
};

foo x{1, 2, 3};
int y[3] = {1, 2, 3};
short z[6] = {1, 0, 2, 0, 3, 0};
```

All look the same in memory!

Other types

- Each type has a *size* and an *alignment*
- Members are placed sequentially, respecting the alignment

Example:

```
struct simple {
  int a{1};
  int b{2};
  int c{3};
  long d{100};
  int e{4};
};
```

a	b
c	*padding*
d	
e	*padding*

Rules (simplified)

1. If a parameter has a copy constructor or a destructor:
   - Pass by hidden reference
2. If a parameter is larger than 4*8 bytes
   - Pass in memory
3. If a parameter uses more than 2 integer registers
   - Pass in memory
4. Otherwise
   - Pass in appropriate registers (integer/floating-point)

AMD64 (SystemV)

```
int fn(int a, int b, int c);          mov $1, %edi
                                      mov $2, %esi
int main() {                          mov $3, %edx
  int r = fn(1, 2, 3);                call fn
}                                     mov %rax, "r"
```

```
      1    2    3                                r

Conclusions

- Passing primitives by value is cheap
- Passing simple types by value is cheap (sometimes cheaper than passing multiple parameters)
  - As long as they are trivially copiable and destructible
  - As long as they are below about 4 machine words or about 64 bytes
- Returning small simple types by value is cheap on AMD64, even without RVO
- Types that are not trivially copiable are more cumbersome: pass them by reference

LINKÖPING
UNIVERSITY

Scenario

```
struct base {
  virtual ~base() = default;

  int data{0x1020};

  virtual void fun(int x) = 0;
};

void much_fun(base &x) {
  x.fun(100);
}
```

How do we know what to call here?

Virtual function tables – vtables (SystemV)

Idea: Put some type info in the objects!

This is called a *virtual function table* or *vtable*:

Offset	Symbol
0	derived::~derived()
8	derived::~derived()
16	derived::fun(int)

Note: More complex for multiple and virtual inheritance!

Virtual function tables – vtables (SystemV)

Idea: Put some type info in the objects!

This is called a *virtual function table* or *vtable*:

Offset	Symbol	
0	derived::~derived()	doesn't call delete
8	derived::~derived()	calls delete
16	derived::fun(int)	

Note: More complex for multiple and virtual inheritance!

Virtual dispatch

```
void much_fun(base &x) {
  x.fun(100);
}
```

```
mov "x", %rdi       ; Put x in a register
mov (%rdi), %rax    ; Read vtable
mov 16(%rax), %rax  ; Read slot #2
mov $100, %rsi      ; Add parameter
call *%rax          ; Call the function
```

Pointers to members

```cpp
class MyClass {
  virtual int virtual_member() { return 1; }
};
class DerivedClass : public MyClass {
  int virtual_member() override { return 1; }
};
int main() {
  auto ptr = &MyClass::virtual_member();
  DerivedClass c;
  return (c.*ptr)(); // Which one is called?
}
```

Pointers to members (SystemV)

Function pointers are fairly straight forward... What about pointers to members?

```
plain_ptr   x = &MyClass::static_member;
member_ptr  y = &MyClass::normal_member;
member_ptr  z = &MyClass::virtual_member;
```

Let's look at their sizes:

```
sizeof(x) == ?;
sizeof(y) == ?;
sizeof(z) == ?;
```

Pointers to members (SystemV)

Function pointers are fairly straight forward... What about pointers to members?

```
plain_ptr  x = &MyClass::static_member;
member_ptr y = &MyClass::normal_member;
member_ptr z = &MyClass::virtual_member;
```

Let's look at their sizes:

```
sizeof(x) == sizeof(void *);
sizeof(y) == sizeof(void *)*2;
sizeof(z) == sizeof(void *)*2;
```

What?

Let's look at the code!

```
call_member:
  mov "ptr.ptr", %rax
  and $1, %rax
  test %rax, %rax
  jne .L12
  mov "ptr.ptr", %rax
  jmp .L13
```

```
.L12:
  mov "ptr.offset", %rax
  add "&c", %rax
  mov (%rax), %rdx
  mov "ptr", %rax
  mov (%rax+%rdx-1), %rax
.L13:
  mov "ptr.offset", %rdi
  add "&c", %rdi
  call *%rax
```

Let's look at the code!

```cpp
struct member_ptr {
  // Pointer or vtable offset
  size_t ptr;

  // Object offset
  size_t offset;
};
```

LINKÖPING
UNIVERSITY

Let's look at the code!

```
void member_call(MyClass &c, member_ptr ptr) {
  void *obj = (void *)&c + ptr.offset;
  void *target = ptr.ptr;
  // Is it a vtable offset?
  if (ptr.ptr & 0x1) {
    void *vtable = *(void **)obj;
    target = *(size_t *)(vtable + ptr - 1);
  }
  // Call the function!
  (obj->*target)();
}
```

Pointers to members

- This is realized differently on x86 on Windows
    - There, *thunks* are used instead.
- This is one of the reasons why you can't just cast member function pointers to void *!
- Pointers to member variables are simpler, they're just the offset of the variable.

What about `typeid`?

```
const type_info &find_typeinfo(base &var) {
  return typeid(var);
}
```

How does the compiler know the actual type of `var`?

Let's look at the code!

```
_Z13find_typeinfoR4base:
    push    %rbp            ; Function prolog
    mov     %rsp, %rbp
    mov     %rdi, %rax      ; First parameter
    movq    (%rax), %rax
    mov     -8(%rax), %rax
    pop     %rbp            ; Function epilog
    ret
```

Let's look at the code!

```
_Z13find_typeinfoR4base:
    push    %rbp            ; Function prolog
    mov     %rsp, %rbp
    mov     %rdi, %rax      ; First parameter
    movq    (%rax), %rax
    mov     -8(%rax), %rax
    pop     %rbp            ; Function epilog
    ret
```

There is something at offset -8 of the vtable!

A closer look at the vtable

```
_ZTV7derived:
  .quad 0
  .quad _ZTI7derived
  .quad _ZN7derivedD1Ev
  .quad _ZN7derivedD0Ev
  .quad _ZN7derived3funEi
```

A closer look at the vtable

Offset	Symbol	
-16	(offset)	
-8	typeinfo for derived	
0	derived::~derived()	doesn't call delete
8	derived::~derived()	calls delete
16	derived::fun(int)	

LINKÖPING
UNIVERSITY

SEH – x86, Win32

Idea: Functions in need of handling exceptions store an entry in a per-thread list of handlers. Essentially:

```
void function () {
  eh_entry entry;
  entry.next = eh_stack;
  entry.handler = &handle_exception;
  eh_stack = &entry;

  // Code as normal

  eh_stack = entry.next;
}
```

  &typeid(B),
  &typeid(A),
}
```

IN.U LINKÖPING
UNIVERSITY

SEH – x86, Win32

Benefits:

- Language agnostic – almost no pre-defined data structures
- Straightforward unwinding

Drawbacks:

- Overhead in all cases – not only when throwing exceptions
- Storing function pointers on the stack...

For AMD64, a solution similar to DWARF is used

DWARF – System V

Idea: Store unwinding information in big tables somewhere!

Each function has an entry containing:

- Unwinding information – How to undo any changes to the stack and/or registers done by the function at any point in the function.
- Personality function – Like in SEH, function that determines if a particular exception is handled and hanles cleanup.
- Additonal data – Any additional information required by the personality function.

DWARF – SystemV

Current: | *exception* |

```
__cxa_begin
_catch
```

f()

saved regs

DWARF table

DWARF – SystemV

DWARF – SystemV

What was thrown?

Well, std::typeinfo is a polymorphic class...

https://itanium-cxx-abi.github.io/cxx-abi/abi.html

```
bool matches(_Unwind_Exception *data) {
  std::type_info *type = /* data->type */;
  // perhaps
  return __dynamic_cast(..., type, &typeid(A), -1);

  // not in the ABI:
  return typeid(A).__do_catch(type, ...);
}
```

DWARF - System V

Benefits:

- Low cost (almost zero) unless exceptions are actually thrown
- Difficult to utilize during buffer overflows

Drawbacks:

- Most functions need to provide unwind information (difficult when doing JIT compilation)
- High cost of actually throwing exceptions

Some interesting functions here:
https://libcxxabi.llvm.org/spec.html

IIU LINKÖPING
UNIVERSITY

Conclusions

- There are many ways of implementing exceptions
- Most are expensive, hopefully only when used!
- Don't use exceptions for normal control-flow!
