External-Parallel Graph Algorithms
Course 01727 Parallel Programming

Parallelism and VLSI Group
Prof. Dr. Jörg Keller

Fachuniversität in Hagen Department of Mathematics and Computer Science

Overview

- External-Memory Algorithms
- Parallel Graph Algorithms
- Application
- Algorithms
- Summary

Slide 2 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

External-Memory Algorithms

- External-memory alg = data set too large to hold in mem
- Data on hard disk:
bandwidth ok for few access patterns
pagewise access
latency high
random access very slow
- Best known example:
external sorting (mostly merge sort, mostly databases)

Slide 3 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Fachuniversität in Hagen Department of Mathematics and Computer Science

Parallel Graph Algorithms I

- Graph representation:
- explicit by adjacency list
- implicit by oracle
- Oracle: call black-box code with node x as parameter obtain $f(x)$ such that $(x, f(x))$ is edge
- Advantage of explicit representation:
graph can be changed, e.g. pointer jumping
- Advantage of implicit representation:
able to handle really large graphs without ext. memory

Slide 4 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Fachuniversität in Hagen Department of Mathematics and Computer Science

Parallel Graph Algorithms II

- Example:
given digraph G with outdegree 1 by oracle
compute strongly connected components (SCCs)
- Two variants:
- indegree also exactly 1 (know function f is bijective)
- indegree may vary (know nothing about function f)

Slide 5 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Fachuniversität in Hagen Department of Mathematics and Computer Science

Application I

- Consider finite state machine accepting no input (except in init phase)
- State graph has outdegree exactly 1
- Examples:
pseudo-random number generator
stream cipher
iterated block cipher
cryptographic hash chain

Slide 6 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Department of Mathematics and Computer Science

Application II

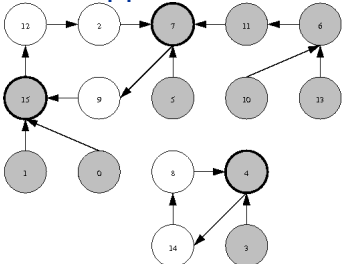

- Oracle = code of state-transition function
- State space typically large: 2^{64} at least
- Strongly connected components = cycles
cycle lengths important parameter wrt security

Department of Mathematics and Computer Science

Application III

Slide 8 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Department of Mathematics and Computer Science

Algorithms I

- List ranking as first exercise
- Given: List of length n in array `succ[1:n]`
end of list points to itself
- Wanted: for each list element, distance to end of list
- For($t=1; t < \log n; t++$)
do in parallel for $i=1..n$ {
 `dist[i] += dist[succ[i]]; succ[i] = succ[succ[i]];`
}

Slide 9 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Department of Mathematics and Computer Science

Algorithms II

- Pointer doubling in external memory:
- Store list of edges $(i, \text{succ}[i])$ twice on external memory
- Sort one copy with i , one copy with `succ[i]`
- For each i :
find predecessor j in 2nd copy, `succ[j] = i` (possibly mult.)
find successor `succ[i]` in 1st copy
write $(j, \text{succ}[i])$ to disc
- Iterate $\log n$ times: $O(n/p * (\log(n))^2)$

Slide 10 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Department of Mathematics and Computer Science

Algorithms III

- Find SCCs of deg1-graph given by oracle f
if each SCC contains a node with property A
- For(all nodes x with property A)
 follow path $x, f(x), f(f(x)) \dots$ till reach node y with A
 write $(x, y, \text{dist}_{x,y})$ to disk
}
do {
 make copy of edge list with reversed edges;
 sort 1st copy with x , sort 2nd copy with y ;
 for each (x, y) in 1st copy:
 write (x, y) to disk if (x, y') in 2nd copy
} while (edges have been removed);

Slide 11 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Department of Mathematics and Computer Science

Algorithms IV

- Algorithm „shaves“ leaves from graph
- May iterate for long, expect distance to cycle $O(\sqrt{n})$
- Therefore: use either if known that graph is shallow
or use until size reduced that fits into main mem

Slide 12 Course 01727 Parallel Programming Parallelism and VLSI Group Prof. Dr. J. Keller

Algorithms V

- Find most cycles (=SCCs) for deg1-graph with bij. oracle f
- Preprocessing:
define as many random anchor nodes as fit on your disks
for(each anchor x){
 follow path $x, f(x), f(f(x)), \dots$ until reach other anchor y
 write to disk $(x, y, dist_{xy})$
}
- Converts graph with oracle into smaller graph with adjacency list
contains only cycles with ≥ 1 anchor

Algorithms VI

- How to detect that node is anchor?

If assumed that deg1-graph is random:
use deterministic anchors e.g. all with 24 zero bits

If not: use additionally pseudorandom permutation π
where $\pi(x)$ and $\pi^{-1}(x)$ can be computed fast
- Why so many anchors that disks are needed?
Chance of putting anchor onto small cycle increases
Find more cycles!

Algorithms VII

- Compute cycles in anchor graph in several rounds
- Each round:
load edges (x, y) from largest x , as fit into main mem
compact all edges with (y, \dots) also in main mem
- Remove references to those edges in edges on disk
- Parallel time: $O((n/m)^2/p)$

Summary

- Ext-mem algorithms gain importance:
large data sets, complex memory hierarchies
- Many ext-mem algorithms use sorting
- Currently: some better algorithms for undirected graphs
- Algorithms very complex
