

# Safety-Critical Computer Systems

Treatment of System Faults  
 Simin Nadjm-Tehrani  
[www.ida.liu.se/~snt](http://www.ida.liu.se/~snt)

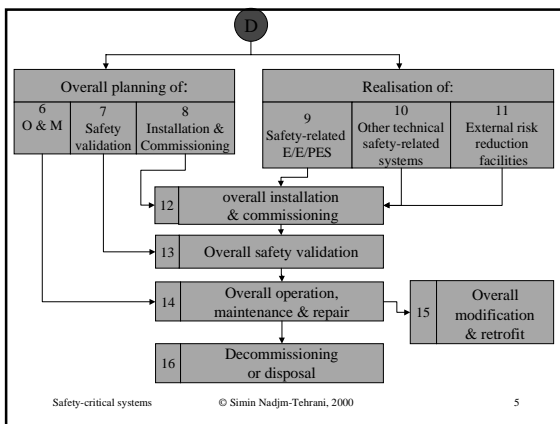

## First some news...

- Groups formed and group meetings planned
- Fault-tree+ installed, can be used for testing and learning
- Last lecture/resource session: discussions with Volvo

## Structure of safety-critical systems

## Overall safety lifecycle (IEC 61508)

But how does this relate to our classical (computer) systems development activities?

## Types of faults

- **Transient**
  - e.g. electromagnetic radiation in environment
- **Intermittent**
  - e.g. loose wire
- **Permanent**
  - e.g. design error, hardware defect

## Verification and validation

- Show that system behaviour is in accordance to requirements specification
  - Inspections
  - Testing
  - Formal verification
- Show that requirements are complete and consistent

## On-line treatment of faults (fault-tolerance)

- **Fault detection**
  - by program or environment
- **Fault containment with the help of redundance in**
  - software
  - hardware
  - data

From article in Edinburgh Review, 1824:  
D. Lardner

*"The most certain and effectual check upon errors which arise in the process of computation is to cause the same computations to be made by separate and independent computers\*; and this check is rendered still more decisive if their computations are carried out by different methods."*

\* *people who compute*

## System architecture

- Highly influences choice of methods for incorporation of redundancy
- Monolithic/Distributed systems
- Synchronous/Asynchronous systems

## Static Redundancy

To be used all the time (whether errors showed up or not), just in case...

- SW: N-version programming
- HW: Voting and masking
- Data: Parity bits, checksums

## N-version programming

- Main problem: to get the different versions to act differently at test instances which are error-inducing
- Night/Leveson experiment:
  - the only errors missed, were missed by all 28 versions!

13

## Dynamic Redundancy

Used when error has occurred and must be contained

- SW: recovery methods
- HW: switch to back-up modules
- Data: self-correcting codes

14

## Error recovery

Backward:

- roll back the system to a safe state which was reached before the error appeared (when did error appear? )
- restart with alternative module (how is the result affected by earlier module 's side effects?)

15

## Error recovery

Forward:

- "fix the error" and continue as if nothing happened
- redundancy lies where one fixes the error

Safety-critical systems

16

## Distributed systems

- Introduce new complications
  - no global clock
  - richer fault models
  - network partitions
- Software replication and group mechanisms
  - transparency in treatment of faults

17

## Exception management

- Every program should test for validity range of its computations, why exceptions?
- Mechanism to support recovery models in programming languages
  - e.g. Ada 's exceptions support backward error recovery via their termination model

18

## Static and dynamic exceptions

- Is there a difference between foreseen and unforeseen faults?
- For foreseeable faults, recover via specific exception handlers, clean up operations
- For unforeseen faults, achieve graceful degradation

19

```
package Temp_Control is
subtype Temperature is integer range 0..100;
Sensor_Dead, Actuator_Dead: exception;
...
end Temp_Control;
package body Temp_Control is

    procedure Set_Temp(...) is
    begin
        -- set new value for actuator
        if No_Response then
            raise Actuator_Dead
        end if;
    end Set_Temp;
    ...
end Temp_Control;
```

20

```
function Read_Temp return Temperature is
begin
    -- read sensor value
    if No_Response then
        raise Sensor_Dead
    end if;
    -- return the value
    exception
        when Constraint_Error =>
            -- too high a temperature
            -- take appropriate action
    end Read_Temp;
    ...
end Temp_Control;
```

21

```
begin
    -- initialize
    Set_Temp(...);
    when Actuator_Dead =>
        -- take some action
    ...
end Temp_Control;
```
