

## Code Generation

Christoph Kessler, IDA,  
Linköpings universitet, 2007.

## Code generation

### Requirements for code generation

- Correctness
- High code quality
- Efficient use of the resources of the target machine
- Quick code generation (for interactive use)
- Retargetability (parameterization in target machine spec.)

### In practice:

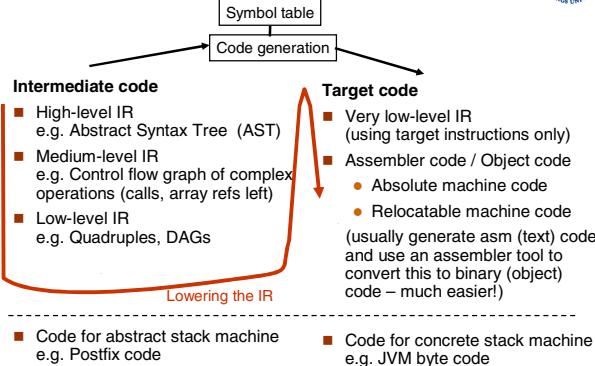

- Difficult to generate good code
- Simple to generate bad code
- There are code generator generators ...

C. Kessler, IDA, Linköpings universitet.

2

TDBB29 / TDBB44: Code Generation

## Intermediate code vs. target code

C. Kessler, IDA, Linköpings universitet.

3

TDBB29 / TDBB44: Code Generation

## Absolute vs. relocatable target code

### Absolute code

- Final memory area for program is statically known
- Hard-code addresses
- Sufficient for very simple (typically, embedded) systems
  - ☺ fast
  - ☺ no separate compilation
  - ☺ cannot call modules from other languages/compilers

### Relocatable code

- Needs relocation table and relocating linker + loader or run-time relocation in MMU
- most flexible

C. Kessler, IDA, Linköpings universitet.

4

TDBB29 / TDBB44: Code Generation

## Stack machines vs. Register machines

Generate code for C assignment       $A = B * C;$

where A, B global, C local var.

On a stack machine:

```

PUSH _A // static address of A
PUSH _B
LOAD   // dereference _B
PUSH fp // stack frame ptr reg
INCR #4 // C at stack adr. FP+4
LOAD
MUL
STORE
    
```

```

LDCONST _A, R1
LDCONST _B, R2
LOAD  R2, R2 // dereference _B
ADD   FP, #4, R3 // addr. of C
LOAD  R3, R3 // dereference &C
MUL   R2, R3, R2
STORE R2, R1
    
```

C. Kessler, IDA, Linköpings universitet.

On a register machine:

## 3 Main Tasks in Code Generation

### Instruction Selection

- Choose set of instructions equivalent to IR code
- Minimize (locally) execution time, # used registers, code size
- Example: INCRM #4(fp) vs. LOAD #4(fp), R1  
ADD R1, #1, R1  
STORE R1, #4(fp)

### Instruction Scheduling

- Reorder instructions to better utilize processor architecture
- Minimize temporary space (#registers, #stack locations) used, execution time, or energy consumption

### Register Allocation

- Keep frequently used values in registers (limited resource!)
  - ➔ Some registers are reserved, e.g. sp, fp, pc, sr, retval ...
- Minimize #loads and #stores (which are expensive instructions!)
- **Register Allocation:** Which variables to keep when in some register?
- **Register Assignment:** In which particular register to keep each?

C. Kessler, IDA, Linköpings universitet.

6

TDBB29 / TDBB44: Code Generation

## Machine model (here: a simple register machine)

**■ Register set**

- E.g. 32 general-purpose registers R0, R1, R2, ... some of them reserved (sp, fp, pc, sr, retval, par1, par2 ...)

**■ Instruction set** with different addressing modes

- Cost (usually, time / latency) depends on the operation and the addressing mode
- Example: PDP-11 (CISC), instruction format  $OP\ src,\ dest$

Source operand	Destination address	Cost
register	register	1
register	memory	2
memory	register	2
memory	memory	3

TDDB44: Code Generation

C. Kessler, IDA, Linköpings universitet.

## Example: $A = B + C;$

- MOVE \_B, R0 ; 2  
ADD \_C, R0 ; 2  
MOVE R0, \_A ; 2 → total cost = 6
- MOVE \_B, \_A ; 3  
ADD \_C, \_A ; 3 → total cost = 6
- (B already in R2, C already in R3, C in R3 not used later)  
ADD R2, R3 ; 1  
MOVE R3, \_A ; 2 → total cost = 3
- (B already in R2, C in R3 and not needed later, A will be kept in R3)  
ADD R2, R3 ; 1 → total cost = 1

There is a lot to be gained with good register allocation!

C. Kessler, IDA, Linköpings universitet. 8 TDDB29 / TDDB44: Code Generation

## Some Code Generation Algorithms

**■ Macro-expansion of IR operations (quadruples)**

**■ "Simple code generation algorithm" (textbook Section 8.6)**

**■ Code generation for expression trees**

- Labeling algorithm [Ershov 1958] [Sethi, Ullman 1970]

**■ Code generation using pattern matching**

- For trees: Aho, Johnsson 1976 (dynamic programming), Graham/Glanville 1978 (LR parsing), Fraser/Hanson/Proebsting 1992 (IBURG tool), ...
- For DAGs: [Ertl 1999], [K., Bednarski 2006] (DP, ILP)

C. Kessler, IDA, Linköpings universitet. 9 TDDB29 / TDDB44: Code Generation

## Macro expansion of quadruples

**■ Each quadruple is translated to a sequence of one or several target instructions that performs the same operation.**

☺ very simple  
☺ bad code quality

- Cannot utilize powerful instructions/addressing modes that do the job of several quadruples in one step
- Poor use of registers

C. Kessler, IDA, Linköpings universitet. 10 TDDB29 / TDDB44: Code Generation

## Simple code generation algorithm (1)

**■ Input:** Basic block graph (quadruples grouped in BB's)

**■ Principle:**  
Keep a (computed) value in a register as long as possible, and move it to memory only

- if the register is needed for another calculation
- at the end of a basic block.

**BB3:**  
( ADD, a, b, x )  
...  
( MUL, x, y, t1 )  
...  
( ASGN, t1, 0, x )  
...

**■ A variable x is used locally after a point p if x's value is used within the block after p before an assignment to x (if any) is made.**

**■ All variables (except temporaries) are assumed to be alive (may be used later before possibly being reassigned) after a basic block.**

C. Kessler, IDA, Linköpings universitet. 11 TDDB29 / TDDB44: Code Generation

## "is used locally" and "alive"

"alive variables"  
is a backward data-flow analysis problem.

5. b, c, e alive  
4. b, c used locally  
3. a, b, d used locally  
2. e is alive  
1. e is used locally

C. Kessler, IDA, Linköpings universitet. 12 TDDB29 / TDDB44: Code Generation

## Simple code generation algorithm (2)

$\text{reg}(R)$ : current content (variable) stored in register R

$\text{adr}(A)$ : list of addresses ("home" memory location, register) where the *current* value of variable A resides

- Generate code for a quadruple  $Q = (\text{op}, B, C, A)$ : ( $\text{op}$  a binary oper.)
- $(RB, RC, RA) \leftarrow \text{getreg}(Q)$ ; // selects registers for B, C, A – see later
- If  $\text{reg}(RB) \neq B$ : generate **LOAD** B, RB;  $\text{reg}(RB) \leftarrow B$ ;  $\text{adr}(B) \leftarrow \text{adr}(B) \cup \{RB\}$
- If  $\text{reg}(RC) \neq C$ : generate **LOAD** C, RC;  $\text{reg}(RC) \leftarrow C$ ;  $\text{adr}(C) \leftarrow \text{adr}(C) \cup \{RC\}$
- generate **OP** RB, RC, RA (where **OP** implements op)  
 $\text{adr}(A) \leftarrow \{RA\}$ ; // old value of A in memory is now stale  
 $\text{reg}(RA) \leftarrow A$ ;
- If B and/or C no longer used locally and are not alive after the current basic block, free their registers RB, RC (update reg, adr)

After all quadruples in the basic block have been processed,  
generate **STOREs** for all non-temporary var's that only reside in a register

C. Kessler, IDA, Linköpings universitet.

13

TDBB29 / TDBB44: Code Generation

## Simple code generation algorithm (3)

**getreg** ( quadruple  $Q = (\text{op}, B, C, A)$  ) determines  $(RB, RC, RA)$ :

- Determine RB:
  - If  $\text{adr}(B)$  contains a register RB and  $\text{reg}(RB) == B$ , then use RB.
  - If  $\text{adr}(B)$  contains a register RB with  $\text{reg}(RB) \neq B$  or  $\text{adr}(B)$  contains no register at all:
    - Use an empty register as RB if one is free.
    - If no register is free: Select any victim register R that does not hold C.
    - $V \leftarrow \{v: R \in \text{adr}(V)\}$  (there may be several v's, due to control flow)
      - If for all v in V,  $\text{adr}(v)$  contains some other place beyond R: OK, use R for RB.
      - If A in V: OK, use R=RA for RB.
      - If all v in V not alive after this basic block and not used locally after Q: OK, use R for RB
      - Otherwise: for each v in V,
        - generate **STORE** R, v; // **spill** register R contents to memory
        - $\text{adr}(v) = \text{adr}(v) - \{R\} \cup \{v\}$ ;
- Determine RC: similarly

14

## Simple code generation algorithm (4)

■ Determine RA: similarly, where...

- Any R with  $\text{reg}(R) = \{A\}$  can be reused as RA
- If B is not used after Q, and  $\text{reg}(RB) = \{B\}$ , can use RA=RB.
- (similarly for C and RC)

C. Kessler, IDA, Linköpings universitet.

15

TDBB29 / TDBB44: Code Generation

## Example

Generate code for this basic block in pseudo-quadruple notation:

```

T1 := a + b;
T2 := c + d;
T3 := e + f;
T4 := T2 * T3;
g := T1 - T4;

```

Initially, no register is used.

Assume a, b, c, d, e, f, g are alive after the basic block,  
but the temporaries are not

Machine model: as above, but only 3 registers R0, R1, R2

(see whiteboard)

TDBB29 / TDBB44: Code Generation

16

## Solution (NB – several possibilities, dep. on victim selection)

1. LOAD a, R0 // now  $\text{adr}(a) = \{\&a, R0\}$ ,  $\text{reg}(R0)=\{a\}$
2. LOAD b, R1
3. ADD R0, R1, R2 // now  $\text{adr}(T1) = \{R2\}$ ,  $\text{reg}(R2)=\{T1\}$   
// reuse R0, R1 for c, d, as a, b still reside in memory  
// use R0 for T2, as c still available in memory.
4. LOAD c, R0
5. LOAD d, R1
6. ADD R0, R1, R0 // now  $\text{adr}(T2) = \{R0\}$ ,  $\text{reg}(R0)=\{T2\}$   
// reuse R1 for e, need a register for f – none free! Pick victim R0
7. STORE R0, 12(fp) // spill R0 to a stack location for T2, e.g. at fp+12
8. LOAD e, R1
9. LOAD f, R0
10. ADD R1, R0, R1 // now  $\text{adr}(T3) = \{R1\}$ ,  $\text{reg}(R1)=\{T3\}$
11. LOAD T2, R0 // reload T2 to R0
12. MUL R0, R1, R0 // T4 in R0
13. SUB R2, R0, R2 // g in R2
14. STORE R2, g

14 instructions,  
including 9 memory accesses  
(2 due to spilling)

C. Kessler, IDA, Linköpings universitet.

17

TDBB29 / TDBB44: Code Generation

## Example – slightly reordered

Generate code for this basic block in pseudo-quadruple notation:

```

T2 := c + d;
T3 := e + f;
T4 := T2 * T3;
T1 := a + b;
g := T1 - T4;

```

Moving T1 := a + b; here does not modify  
the semantics of the code. (Why?)

Initially, no register is used.

Assume a, b, c, d, e, f, g are alive after the basic block,  
but the temporaries are not

Machine model: as above, but only 3 registers R0, R1, R2

(see whiteboard)

TDBB29 / TDBB44: Code Generation

18

## Solution for reordered example

```

1. LOAD c, R0
2. LOAD d, R1
3. ADD R0, R1, R2 // now adr(T2)=(R2), reg(R2)=(T2)
// reuse R0 for e, R1 for f:
4. LOAD e, R0
5. LOAD f, R1
6. ADD R0, R1, R0 // now adr(T3) = {R0}, reg(R0)=(T3)
// reuse R0 for T4:
7. MUL R0, R1, R0 // now adr(T4)=(R0), reg(R0)=(T4)
// reuse R1 for a, R2 for b, R1 for T1:
8. LOAD a, R1
9. LOAD b, R2
10. ADD R1, R2, R1 // now adr(T1) = {R1}, reg(R1)=(T1)
// reuse R1 for g:
11. SUB R1, R0, R1 // g in R1
12. STORE R1, g

```

```

T2 := c + d;
T3 := e + f;
T4 := T2 * T3;
T1 := a + b;
g := T1 - T4;

```

12 instructions,  
including 7 memory accesses

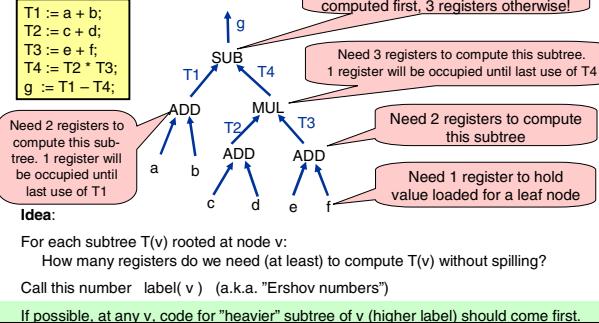

No spilling! Why?

C. Kessler, IDA, Linköpings universitet.

19

## Explanation

- Consider the **data flow graph** (here, an expression tree) of the example:

## Labeling algorithm [Ershov 1958]

- Yields **space-optimal code** (proof: [Sethi, Ullman 1970]) (using a minimum #registers **without spilling**, or min. # stack locations) for expression **trees**.
  - (Time is fixed as no spill code is generated.)
- The problem is NP-complete for expression DAGs! [Sethi'75]
  - Solutions for DAGs: [K., Rauber '95], [K. '98], [Amaral et al.'00]
- If #machine registers exceeded: Spill code could be inserted afterwards for excess registers, but not necessarily (time-) optimal then...

2 phases:

- Labeling phase**
  - bottom-up traversal of the tree
  - computes  $\text{label}(v)$  recursively for each node  $v$
- Code generation phase**
  - top-down traversal of the tree
  - recursively generating code for heavier subtree first

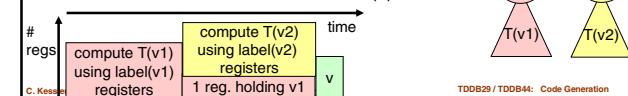

C. Kessler, IDA, Linköpings universitet.

21

## Labeling phase

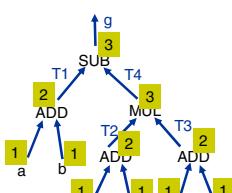

Bottom-up, calculate the register need for each subtree  $T(v)$ :

- If  $v$  is a leaf node,  $\text{label}(v) \leftarrow 1$
- If  $v$  is a unary operation with operand node  $v_1$ ,  $\text{label}(v) \leftarrow \text{label}(v_1)$
- If  $v$  is a binary operation with operand nodes  $v_1, v_2$ :
  - $m \leftarrow \max(\text{label}(v_1), \text{label}(v_2))$ ;
  - if ( $\text{label}(v_1) = \text{label}(v_2)$ )  $\text{label}(v) \leftarrow m + 1$ ;
  - else  $\text{label}(v) \leftarrow m$ ;

TDBB29 / TDBB44: Code Generation

## Example – labeling phase

C. Kessler, IDA, Linköpings universitet.

23

TDBB29 / TDBB44: Code Generation

## Code generation phase

- Register stack **freereg**s of currently free registers, initially full
- Register assignment function **reg** from values to registers, initially empty
- gencode(v)** { // generate space-optimal code for subtree  $T(v)$ 
  - If  $v$  is a leaf node:
    - $R \leftarrow \text{freereg.pop}(); \text{reg}(v) \leftarrow R$ ; // get a free register  $R$  for  $v$
    - generate( **LOAD**  $v, R$  );
  - If  $v$  is a unary node with operand  $v_1$  in a register  $\text{reg}(v_1)=R_1$ :
    - generate( **OP**  $R_1, R_1$  );  $\text{reg}(v) \leftarrow R_1$ ;
  - If  $v$  is a binary node with operands  $v_1, v_2$  in  $\text{reg}(v_1)=R_1, \text{reg}(v_2)=R_2$ :
    - if ( $\text{label}(v_1) \geq \text{label}(v_2)$ ) // code for  $T(v_1)$  first:
      - gencode(v1);**
      - gencode(v2);**
    - else
      - gencode(v2);**
      - gencode(v1);**
    - generate( **OP**  $R_1, R_2, R_1$  );
    - freereg.push(R\_2);** // return register  $R_2$ , keep  $R_1$  for  $v$

C. Kessler, IDA, Linköpings universitet.

24

TDBB29 / TDBB44: Code Generation

## Remarks on the Labeling Algorithm

- Still one-to-one or one-to-many translation from quadruple operators to target instructions
- The code generated by gencode() is **contiguous** (a subtree's code is never interleaved with a sibling subtree's code).
  - E.g., code for a unary operation v immediately follows the code for its child v1.
  - Good for space usage, but bad for execution time on pipelined processors!
  - There are expression DAGs for which a non-contiguous code exists that uses fewer registers than any contiguous code for it. [K., Rauber 1995]
- The labeling algorithm can serve as a heuristic (but not as optimal algorithm) for DAGs if gencode() is called for common subexpressions only at the first time.

C. Kessler, IDA, Linköpings universitet.

25

TDBB29 / TDBB44: Code Generation

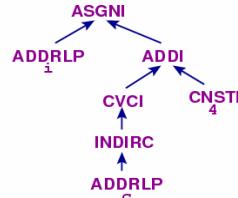

## Towards code generation by pattern matching

- Example: Data flow graph (expression tree) for  $i = c + 4$

- in LCC-IR (DAGs of quadruples) [Fraser,Hanson'95]
- i, c: local variables

{ int i; char c; i=c+4; }

### In quadruple form:

(Convention: last letter of opcode gives result type: I=int, C=char, P=pointer)

(ADDRLP, i, 0, t1)	// t1 ← fp+4
(ADDRLP, c, 0, t2)	// t2 ← fp+12
(INDIRC, t2, 0, t3)	// t3 ← M(t2)
(CVCI, t3, 0, t4)	// convert char to int
(CNSTI, 4, 0, t5)	// create int-const 4
(ADDI, t4, t5, t6)	
(ASGNI, t6, 0, t1)	// M(t1) ← t6

26

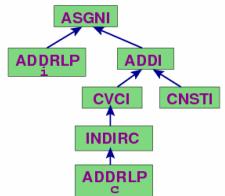

TDBB29 / TDBB44: Code Generation

## Recall: Macro Expansion

- For the example tree:
  - s1, s2, s3...: "symbolic" registers (allocated but not assigned yet)
  - Target processor has delayed load (1 delay slot)

{ int i; char c; i=c+4; }

naive instruction selection,  
arranged by a postorder traversal:

```

addi fp,#4,s1 ! ADDRLP(i)
addi fp,#8,s2 ! ADDRLP(c)
load 0(s2),s3 ! INDIRC
nop ! ", delay slot
! CVCI
addi R0,#4,s4 ! CNSTI
addi s3,s4,s5 ! ADDI
store s4,0(s1) ! ASGNI
(needs 7cc)
  
```

27

TDBB29 / TDBB44: Code Generation

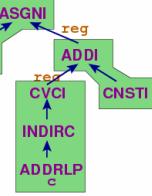

## Using tree pattern matching...

- Utilizing the available addressing modes of the target processor, 3 instructions and only 2 registers are sufficient to cover the entire tree:

{ int i; char c; i=c+4; }

pattern-matching instruction selection,  
arranged by a postorder traversal:

```

load 8(fp),s3 ! ADDRPF+INDIRC+CVCI
nop ! ", delay slot
addi s3,#4,s4 ! CNSTI+ADDI
store s4,4(fp) ! ADDRPF(i)+ASGNI
(needs 4cc)
  
```

28

TDBB29 / TDBB44: Code Generation

## Code generation by pattern matching

- Powerful target instructions / addressing modes may cover the effect of several quadruples in one step.
- For each instruction and addressing mode, define a pattern that describes its behavior in terms of quadruples resp. data-flow graph nodes and edges (usually limited to tree fragment shapes: **tree pattern**).
- A pattern **matches** at a node v if pattern nodes, pattern operators and pattern edges coincide with a tree fragment rooted at v
- Each instruction (tree pattern) is associated with a **cost**, e.g. its time behavior or space requirements
- Optimization problem:** Cover the entire data flow graph (expression tree) with matching tree patterns such that each node is covered **exactly once**, and the accumulated cost of all covering patterns is minimal.

C. Kessler, IDA, Linköpings universitet.

29

TDBB29 / TDBB44: Code Generation

## Tree grammar (Machine grammar)

The target processor is described by a **tree grammar**  $G = (N, T, s, P)$

nonterminals  $N = \{ \text{stmt}, \text{reg}, \text{con}, \text{addr}, \text{mem}, \dots \}$  (start symbol is stmt)

terminals  $T = \{ \text{CNSTI}, \text{ADDRLP}, \dots \}$

production rules  $P$ :

	target instruction for pattern	cost
reg → ADDI( reg, con )	addi %r,%c,%r	1
reg → ADDI( reg, reg )	addi %r,%r,%r	1
stmt → ASGNI( addr, reg )	store %r,%a	1
stmt → ASGNI( reg, reg )	store %r,0(%r)	1
reg → ADDRLP	addi fp,#%d,%r	1
addr → ADDRLP	%d(fp)	0
reg → addr	addi %a,%r	1
reg → INDIRC( addr )	load %a,%r; nop	2
reg → INDIRC( reg )	load 0(%r),%r; nop	2
reg → CVCI(INDIRC( addr ))	load %a,%r; nop	2
reg → CVCI(INDIRC( reg ))	load 0(%r),%r; nop	2
con → CNSTI	%d	0
reg → con	addi R0,#%c,%r	1

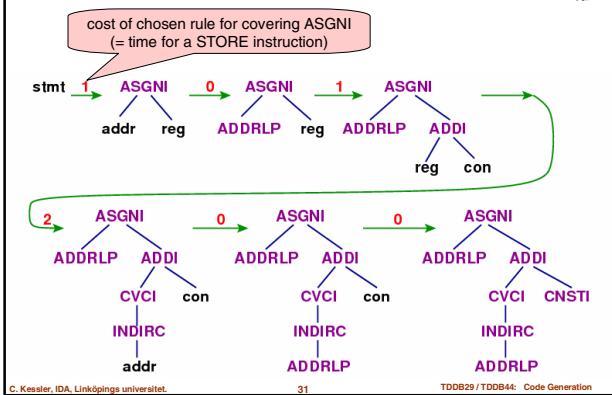

C. Kessler, IDA, Linköpings universitet.

30

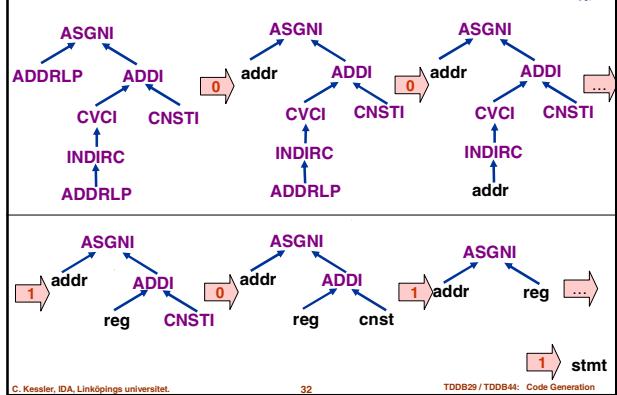

TDBB29 / TDBB44: Code Generation

## Derivation of the expression tree

## Derivation using a LR parser:

## Some methods for tree pattern matching

- Use a LR-parser for matching [Graham, Glanville 1978]
    - ⌚ compact specification of the target machine using a context-free grammar ("machine grammar")
    - ⌚ quick matching
    - ⌚ not total-cost aware
      - (greedy local choices at reduce decisions → suboptimal)
  - Combine tree pattern matching with dynamic programming for total cost minimization (→ TDDC86)
    - [Aho, Ganapathi, Tjiang '89] [Fraser, Hanson, Proebsting'92]
  - A LR parser is stronger than what is really necessary for matching tree patterns in a tree.
    - Right machine model is a **tree automaton**
      - = a finite automaton operating on input *trees* rather than flat strings [Ferdinand, Seidl, Wilhelm '92]
  - By Integer Linear Programming [Wilson et al. '94] [K., Bednarski '06]
