## 1 Sorting

### 1.1 Heap-sort

#### Sorting with priority queues

- Use a priority queue to sort a collection of comparable elements
  - Insert an element with a serie of insertion operations
  - Remove the elements in sorted order with a series of operations `removeMin`
- The runtime depends on the implementation of the priority queue:
  - Unsorted sequences give a selection sort and  $O(n^2)$  time
  - Sorted sequences give insertion sorting and  $O(n^2)$  time

```

procedure PQSORT(S)
  P ← empty priority queue
  while ¬S.ISEMPTY() do
    e ← S.REMOVE(S.FIRST())
    P.INSERT(e)
  while ¬P.ISEMPTY() do
    e ← P.REMOVEDMIN()
    S.INSERTLAST(e)

```

### The height of a heap

**Proposition 1.** The height of a heap storing  $n$  keys is  $O(\log n)$

*Bevis.* We use a heap as a complete binary tree.

- Let  $h$  be the height of a heap storing  $n$  keys
- Since there are  $2^i$  keys at depth  $i = 0, \dots, h-1$  and at least one key in depth  $h$  we get  $n \geq 1 + 2 + 4 + \dots + 2^{h-1} + 1$
- Thus  $n \geq 2^h$ , i.e.  $h \leq \log_2 n$

□

djup nycklar

### Insertion in a heap

- The method `insert` in an ADT priority queue corresponds to the insertion of key  $k$  in the heap
- The insertion algorithm consists of three steps
  - Find the place to insert  $z$  (the new last leaf)
  - Store  $k$  in  $z$
  - Reset the heap property

### Upheap

- After inserting a new key  $k$ , it is not certain that the heap property is still fulfilled
- The method `upheap` restores the heap property by swapping  $k$  along the upward path from the inserted node
- `upheap` terminates when the key  $k$  reaches the root or a node whose parent has a key that is not greater than  $k$
- Since the height of a heap is  $O(\log n)$ , `upheap` runs in  $O(\log n)$  time

## Removal from a heap

- Method `removeMin` consists in removing the root key from the heap
- Removal algorithm consists of three steps
  - Replace the root key with the key in the last leaf  $w$
  - remove  $w$
  - Reset the heap property

21.7

## Downheap

- After replacement of the root key with key  $k$  from the last leaf, it is not certain that the heap property is still fulfilled
- Method `downheap` restores the heap property by swapping  $k$  along the downward path of the insertion node
- `downheap` terminates when the key  $k$  reaches a leaf or a node whose children have keys that are not less than  $k$
- Since the height of a heap is  $O(\log n)$ , `downheap` runs in time  $O(\log n)$

21.8

## Heap-sort

- Consider a priority queue with  $n$  elements implemented in terms of a heap
  - memory utilization is  $O(n)$
  - `insert` and `removeMin` run in  $O(\log n)$  time
  - `size`, `isEmpty` and `min` run in  $O(1)$  time
- Upon the utilization of heap-based priority queue we can sort a sequence of  $n$  elements in  $O(n \log n)$  time
- The resulting algorithm is called heap-sort
- Heap-sort is much faster than quadratic sorting algorithms

21.9

### Combine 2 heaps

- Given 2 heaps and a key  $k$
- Create a new heap where the root node stores the key  $k$ , and the two given heaps as subtrees
- Run **downheap** to reset the heap property

21.10

### Example: construction of a heap bottom-up

21.11

### Example: construction of a heap bottom-up

21.12

Example: construction of a heap bottom-up

21.13

Example: construction of a heap bottom-up

21.14

Analysis

- We visualize the worst case time for a call to **downheap** with a path that first goes to the right, and then repeatedly go left to the bottom of the heap
- Since each node is traversed by at most two such paths, the total number of paths is  $O(n)$
- Thus, the time to construct a heap bottom-up is  $O(n)$
- This construction method is faster than the  $n$  repeated deposits and makes the first phase of heap-sort more efficient

21.15

1.2 Merge-sort

Divide and conquer

- Merge-sort is a sort algorithm based on divide and conquer
- Like the heap-sort

- the execution time is  $O(n \log n)$
- different heap-sort
  - does not use priority queues to help
  - access the data in a sequential manner (suitable to sort the data on disk)

### Merge-sort

Merge-sort on an input sequence  $S$  having  $n$  elements is performed in 3 steps:

- Divide: split  $S$  into 2 sequences  $S_1$  and  $S_2$  each with  $n/2$  elements
- Conquer: sort  $S_1$  and  $S_2$  recursively
- Combine: merge  $S_1$  and  $S_2$  in a unique sorted sequence

**procedure** MERGESORT( $S$ )

**if**  $S.SIZE() > 1$  **then**

$(S_1, S_2) \leftarrow PARTITION(S.SIZE()/2)$

  MERGESORT( $S_1$ )

  MERGESORT( $S_2$ )

$S \leftarrow MERGE(S_1, S_2)$

### Merge two sorted sequences

- Merge 2 sequences  $A$  and  $B$  to form a sequence  $S$  containing the union of elements in  $A$  and  $B$
- Merging 2 sorted sequences, each with  $n/2$  elements, implemented with double linked lists takes  $O(n)$  time

**function** MERGE( $A, B$ )

$S \leftarrow$  empty sequence

**while**  $\neg A.ISEMPTY() \wedge \neg B.ISEMPTY()$  **do**

**if**  $A.FIRST.ELEMENT() < B.FIRST.ELEMENT()$  **then**

$S.INSERTLAST(A.REMOVE(A.FIRST()))$

**else**

$S.INSERTLAST(B.REMOVE(B.FIRST()))$

**while**  $\neg A.ISEMPTY()$  **do**

$S.INSERTLAST(A.REMOVE(A.FIRST()))$

**while**  $\neg B.ISEMPTY()$  **do**

$S.INSERTLAST(B.REMOVE(B.FIRST()))$

**return**  $S$

### Merge-sort tree

- The execution of merge-sort can be visualized as a binary tree
  - Each node represents a recursive call to merge-sort and stores
    - \* unsorted sequence before the execution and its partition
    - \* Sorted sequence after the execution
  - The root is the origin of the call
  - The leaves are calls on partial sequences of size 0 or 1

21.29

2 A lower limit for the comparison based sorting

comparison based sorting

- Many sorting algorithms are *comparison-based*
  - They sort through comparisons between pairs of objects
  - Example: insertion-sort, selection-sort, heap-sort, merge-sort, quick-sort, ...
- Let us therefore try to derive a lower limit for the execution time in the worst case for each algorithm using the comparison to sort  $n$  elements  $x_1, x_2, \dots, x_n$

21.30

Calculating comparisons

- Let's just count comparisons
- Every possible execution of an algorithm is represented by a root-to-leaf path in a *decision tree*

21.31

Example: Decision tree

Sort  $\langle x_1, x_2, \dots, x_n \rangle$

- Each internal node is marked  $i : j$  for  $i, j \in \{1, 2, \dots, n\}$
- The left subtree shows subsequent comparisons if  $x_i \leq x_j$
  - The right subtree shows subsequent comparisons if  $x_i \geq x_j$

21.32

Example: Decision tree

Sort  $\langle x_1, x_2, x_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

- Each internal node is marked  $i : j$  for  $i, j \in \{1, 2, \dots, n\}$
- The left subtree shows subsequent comparisons if  $x_i \leq x_j$
  - The right subtree shows subsequent comparisons if  $x_i \geq x_j$

21.33

Example: Decision tree

Sort  $\langle x_1, x_2, x_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

- Each internal node is marked  $i : j$  for  $i, j \in \{1, 2, \dots, n\}$
- The left subtree shows subsequent comparisons if  $x_i \leq x_j$
  - The right subtree shows subsequent comparisons if  $x_i \geq x_j$

21.34

Example: Decision tree

Sort  $\langle x_1, x_2, x_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

Each internal node is marked  $i : j$  for  $i, j \in \{1, 2, \dots, n\}$

- The left subtree shows subsequent comparisons if  $x_i \leq x_j$
- The right subtree shows subsequent comparisons if  $x_i \geq x_j$

Example: Decision tree

Sort  $\langle x_1, x_2, x_3 \rangle$   
 $= \langle 9, 4, 6 \rangle$ :

Each leaf contains a permutation  $\langle \pi(1), \pi(2), \dots, \pi(n) \rangle$  to indicate that the order  $x_{\pi(1)} \leq x_{\pi(2)} \leq \dots \leq x_{\pi(n)}$  has been established

Decision tree model

A decision tree can model the execution of the comparison-based sorting algorithms:

- A tree for each size of the input data
- Consider the algorithm execution to be shared whenever two elements are compared
- The tree contains all comparisons along all the possible consequences of instructions
- The running time of the algorithm = the length of the path traversed
- The running time in the worst case = the height of the tree

The height of a decision tree

- The height of the decision tree is a lower limit on the execution time in the worst case
- Every possible permutation of the input should lead to a separate output leaf
- Since there is  $n! = 1 \cdot 2 \cdot \dots \cdot n$  leaves, the height of a tree is at least  $\log(n!)$

### 3 Sorting in linear time?

#### 3.1 Counting-sort

Counting sort

**Require:**  $A[1, \dots, n]$ , where  $A[j] \in \{1, 2, \dots, k\}$

**function** COUNTINGSORT( $A$ )

Array to count :  $C[1, \dots, k]$

Array to store the result:  $Res[1, \dots, n]$

**for**  $i \leftarrow 1$  **to**  $k$  **do**

$C[i] \leftarrow 0$

**for**  $j \leftarrow 1$  **to**  $n$  **do**

$C[A[j]] \leftarrow C[A[j]] + 1$

$\triangleright C[i] = |\{nyckel = i\}|$

**for**  $i \leftarrow 2$  **to**  $k$  **do**

$C[i] \leftarrow C[i] + C[i - 1]$

$\triangleright C[i] = |\{nyckel \leq i\}|$

**for**  $j \leftarrow n$  **downto**  $1$  **do**

$Res[C[A[j]]] \leftarrow A[j]$

$C[A[j]] \leftarrow C[A[j]] - 1$

**return**  $Res$

Example

# Counting-sort

21.40

Example

## Loop 1

**for**  $i \leftarrow 1$  **to**  $k$  **do**  
     $C[i] \leftarrow 0$

21.41

Example

## Loop 2

	1	2	3	4	5
A:	4	1	3	4	3

	1	2	3	4
C:	0	0	0	1

Res:					
------	--	--	--	--	--

**for**  $j \leftarrow 1$  **to**  $n$  **do**

$C[A[j]] \leftarrow C[A[j]] + 1 \triangleright C[i] = |\{\text{nyckel} = i\}|$

21.42

Example

## Loop 2

	1	2	3	4	5
A:	4	1	3	4	3

	1	2	3	4
C:	1	0	0	1

Res:					
------	--	--	--	--	--

**for**  $j \leftarrow 1$  **to**  $n$  **do**

$C[A[j]] \leftarrow C[A[j]] + 1 \triangleright C[i] = |\{\text{nyckel} = i\}|$

21.43

Example

## Loop 2

	1	2	3	4	5
A:	4	1	3	4	3

	1	2	3	4
C:	1	0	1	1

Res:					
------	--	--	--	--	--

**for**  $j \leftarrow 1$  **to**  $n$  **do**

$C[A[j]] \leftarrow C[A[j]] + 1 \triangleright C[i] = |\{\text{nyckel} = i\}|$

21.44

Example

## Loop 2

	1	2	3	4	5
A:	4	1	3	4	3

	1	2	3	4
C:	1	0	1	2

Res:					
------	--	--	--	--	--

**for**  $j \leftarrow 1$  **to**  $n$  **do**

$C[A[j]] \leftarrow C[A[j]] + 1 \triangleright C[i] = |\{\text{nyckel} = i\}|$

21.45

Example

## Loop 2

	1	2	3	4	5
A:	4	1	3	4	3

	1	2	3	4
C:	1	0	2	2

Res:					
------	--	--	--	--	--

for  $j \leftarrow 1$  to  $n$  do

$C[A[j]] \leftarrow C[A[j]] + 1 \triangleright C[i] = |\{\text{nyckel} = i\}|$

21.46

Example

## Loop 3

	1	2	3	4	5
A:	4	1	3	4	3

	1	2	3	4
C:	1	0	2	2

Res:					
------	--	--	--	--	--

C':	1	1	2	2
-----	---	---	---	---

for  $i \leftarrow 2$  to  $k$  do

$C[i] \leftarrow C[i] + C[i-1] \triangleright C[i] = |\{\text{nyckel} \leq i\}|$

21.47

Example

## Loop 3

	1	2	3	4	5
<i>A</i> :	4	1	3	4	3

	1	2	3	4
<i>C</i> :	1	0	2	2

<i>Res</i> :					
--------------	--	--	--	--	--

<i>C'</i> :	1	1	3	2
-------------	---	---	---	---

for  $i \leftarrow 2$  to  $k$  do

$C[i] \leftarrow C[i] + C[i-1]$   $\triangleright C[i] = |\{\text{nyckel} \leq i\}|$

21.48

Example

## Loop 3

	1	2	3	4	5
<i>A</i> :	4	1	3	4	3

	1	2	3	4
<i>C</i> :	1	0	2	2

<i>Res</i> :					
--------------	--	--	--	--	--

<i>C'</i> :	1	1	3	5
-------------	---	---	---	---

for  $i \leftarrow 2$  to  $k$  do

$C[i] \leftarrow C[i] + C[i-1]$   $\triangleright C[i] = |\{\text{nyckel} \leq i\}|$

21.49

Example

## Loop 4

**for**  $j \leftarrow n$  **downto** 1 **do**  
   $Res[C[A[j]]] \leftarrow A[j]$   
   $C[A[j]] \leftarrow C[A[j]] - 1$

21.50

Example

## Loop 4

**for**  $j \leftarrow n$  **downto** 1 **do**  
   $Res[C[A[j]]] \leftarrow A[j]$   
   $C[A[j]] \leftarrow C[A[j]] - 1$

21.51

Example

## Loop 4

**for**  $j \leftarrow n$  **downto** 1 **do**  
     $Res[C[A[j]]] \leftarrow A[j]$   
     $C[A[j]] \leftarrow C[A[j]] - 1$

21.52

Example

## Loop 4

**for**  $j \leftarrow n$  **downto** 1 **do**  
     $Res[C[A[j]]] \leftarrow A[j]$   
     $C[A[j]] \leftarrow C[A[j]] - 1$

21.53

Example

# Loop 4

```

for  $j \leftarrow n$  downto 1 do
   $Res[C[A[j]]] \leftarrow A[j]$ 
   $C[A[j]] \leftarrow C[A[j]] - 1$ 
  
```

21.54

## Analysis

$\Theta(k)$  { **for**  $i \leftarrow 1$  **to**  $k$  **do**  
 $C[i] \leftarrow 0$

$\Theta(n)$  { **for**  $j \leftarrow 1$  **to**  $n$  **do**  
 $C[A[j]] \leftarrow C[A[j]] + 1$

$\Theta(k)$  { **for**  $i \leftarrow 2$  **to**  $k$  **do**  
 $C[i] \leftarrow C[i] + C[i-1]$

$\Theta(n)$  { **for**  $j \leftarrow n$  **downto** 1 **do**  
 $Res[C[A[j]]] \leftarrow A[j]$   
 $C[A[j]] \leftarrow C[A[j]] - 1$

---

$\Theta(n + k)$

21.55

## Execution time

If  $k \in O(n)$  the counting sort takes  $\Theta(n)$  time

- But sorting takes  $\Omega(n \log n)$  time!
- What is wrong?

Answer

- *comparison-based sort* takes  $\Omega(n \log n)$  time
- Counting-sort is *not* comparison-based
- In fact, not a single comparison performed between some elements!

21.56

## Stable sorting

Counting-sort is a **stable** sorting method: it preserves the input order of equal elements

**To think about:**

What are the other stable sorting methods?

**3.2 Bucket-sort**

**Bucket-sort**

- Let  $S$  be a sequence of  $n$  elements (key, value) with keys from  $[0, N - 1]$
- Bucket-sort uses the keys as indexes in a help array  $B$  of sequences
  - Phase 1: Empty the sequence  $S$  by moving each item  $(k, v)$  last in its bucket  $B[k]$
  - Phase 2: For  $i = 0, \dots, N - 1$  move items in bucket  $B[i]$  to the end of the sequence  $S$
- Analysis:
  - Phase 1 runs for  $O(n)$  time
  - Phase 2 runs for  $O(n + N)$  time

Bucket-sort runs for  $O(n + N)$  time

**procedure BUCKETSORT( $S, N$ )**

$B \leftarrow$  array with  $N$  empty sequences

**while**  $\neg S$ .ISEMPTY() **do**

$f \leftarrow S$ .FIRST()

$(k, o) \leftarrow S$ .REMOVE( $f$ )

$B[k]$ .INSERTLAST( $(k, o)$ )

**for**  $i \leftarrow 0$  **to**  $N - 1$  **do**

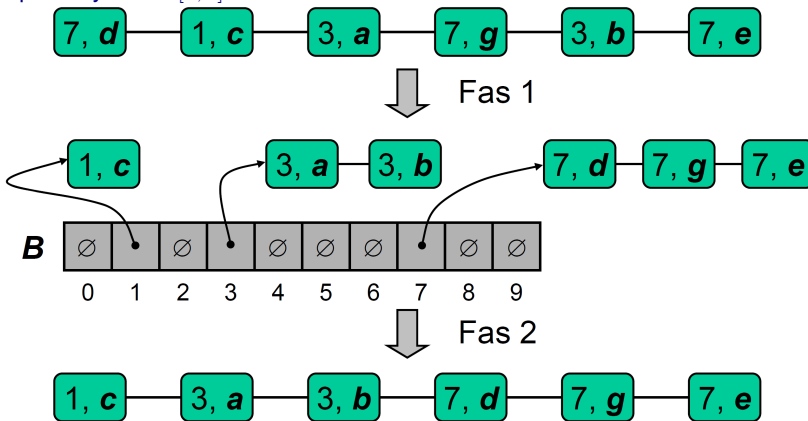

**while**  $\neg B[i]$ .ISEMPTY() **do**

$f \leftarrow B[i]$ .FIRST()

$(k, o) \leftarrow B[i]$ .REMOVE( $f$ )

$S$ .INSERTLAST( $(k, o)$ )

Example: Keys from  $[0, 9]$

**3.3 Radix-sort**

**Radix-sort**

- Origin: Herman Holleriths card sorting machine for census 1890 in USA
- Holleriths original idea: sort the most significant digit first
- Good idea: sort of *least significant digits first* with an external *stable* sorting routine

Example: Execution of radix-sort

Correctness of radix-sort

Use of induction on the digits position

- Suppose that the numbers are sorted on their  $t - 1$  lowest digits
- Sort based on digit  $t$

Correctness of radix-sort

Use of induction on the digits position

- Suppose that the numbers are sorted on their  $t - 1$  lowest digits
- Sort based on digit  $t$ 
  - Two numbers that differ in the number  $t$  is correctly sorted

### Correctness of radix-sort

Use of induction on the digits position

- Suppose that the numbers are sorted on their  $t - 1$  lowest digits
- Sort based on digit  $t$ 
  - Two numbers that differ in the number  $t$  are correctly sorted
  - Two numbers that are equal in number  $t$  get the same order as in the input data  $\Rightarrow$  right order

### Analysis of radix-sort

- Suppose the counting-sort is used as an external sorting routine
- Sort  $n$  machine word on  $b$  bits each
- We can see that every word has  $b/r$  characters in base  $2^r$

Example:

32-bit words 

8	8	8	8
---	---	---	---

$r = 8 \Rightarrow b/r = 4$  pass of counting-sort on digits in base  $2^8$

or  $r = 16 \Rightarrow b/r = 2$  pass of counting-sort on digits in base  $2^{16}$

How many pass we should do?

### Analysis of radix-sort

Remember: counting-sort runs for  $\Theta(n+k)$  time to sort  $n$  numbers from  $[0, k-1]$ . If every  $b$ -bit word is broken up into  $r$ -bit pieces, each takes pass of the counting-sort takes  $\Theta(n+2^r)$ . since there are  $b/r$  pass we get

$$T(n, b) = \Theta\left(\frac{b}{r}(n+2^r)\right)$$

Choose  $r$  to minimize  $T(n, b)$

- Raising  $r$  with few passes, but when  $r \gg \log n$  time increases exponentially.

21.66

### Choosing $r$

$$T(n, b) = \Theta\left(\frac{b}{r}(n+2^r)\right)$$

Minimizing  $T(n, b)$  by differentiate and set it to 0. Or, note that we do not want to have  $2^r \gg n$ , it does not harm asymptotically to choose  $R$  as large as possible given the conditions. The choice  $r = \log n$  means  $T(n, b) = \Theta(bn/\log n)$ .

- For a number in the interval 0 to  $n^d - 1$  we get  $b = d \log n \Rightarrow$  radix-sort runs in  $\Theta(dn)$  time.

21.67

### Conclusions

In practice, radix-sort is fast for large inputs, as well as easy to code and maintain.

*Example: 32-bits number*

- At most 3 passes when sorting  $\geq 2000$  numbers.
- Merge-sort and quick-sort use at least  $\lceil \log 2000 \rceil = 11$  pass.

*Drawback:* It is not possible to sort in-place the counting sort.

21.68
