

CORE Install Ubuntu 16.04

Install and update Ubuntu 16.04 LTS desktop (64-bit PC).

- If creating a VM you probably want 2+ CPUs, 2+GB RAM, 20GB or more HDD, depending on your host system.
- This was tested using VirtualBox 5.1.6 on Mac OS X 10.11.6 El Capitan. VirtualBox guest additions were also installed.

Install Latest Open Source CORE

Dependencies

Install dependency packages using apt-get:

```
sudo apt-get install bash bridge-utils ebttables iproute libtk-img python tcl8.5 tk8.5 autoconf automake gcc libev-dev make pkg-config python-dev libreadline-dev imagemagick help2man
```

Install Quagga with MDR (for MANET routing):

```
wget http://downloads.pf.itd.nrl.navy.mil/ospf-manet/quagga-0.99.21mr2.2/quagga-mr_0.99.21mr2.2_amd64.deb
sudo dpkg -i quagga-mr_0.99.21mr2.2_amd64.deb
```

Latest CORE Source from NRL (alternately, use Github)

This installs the latest CORE source from NRL Subversion (tested using file retrieved on 10/5/16):

```
wget http://downloads.pf.itd.nrl.navy.mil/core/source/nightly_snapshots/core-svnsnap.tgz
tar xzvf core-svnsnap-20160930.tgz
mv core core-20160930
cd core-20160930
./bootstrap.sh
./configure
make -j4
# this puts the GUI under /usr/local/lib/core
# Python module under /usr/local/lib/python2.7/dist-packages/
# binaries under /usr/local/sbin/core-daemon,vnoded,vcmd and /usr/local/bin/core-gui
sudo make install
```

Test Your CORE Install

In one terminal, start the backend using:

```
sudo core-daemon
```

In a second terminal, launch the GUI:

```
core-gui
```

Open and run the sample scenario:

- Choose *File > Open > sample1.imn*
- Press the start button (green arrow)
- Choose *Widgets > Adjacency > OSPFv2 >* and wait for blue lines (OSPF routing convergence)
- double-click **n11** (laptop in upper-left)
- Type in terminal: `ping 10.0.0.7`
- Drag e.g. **n7** in and out of range to start/stop pings.

If the above ping succeeds, your CORE install is good to go.

Terminal

CORE (44996 on ubuntu1604) sample1.imn
