# Challenge 5

Filip Strömbäck, Ahmed Rezine

March 6, 2025

#### Instructions

You have to do research on the parts you do not understand. When you solve problems, do not hesitate to:

- State your starting point. What do you know from start? Why is it important?
- State your goal. What do you need to know to reach it?
- State your assumptions. What are you taking for granted or assuming?
- Show step by step how you can go from what you have to what you want.

You will get one credit for each presentation you claim prepared. You may (at random) be selected to present any of the solutions you prepared. When you are selected for presentation:

- For each step in your solution, explain what you were thinking. How did you come up with this? What gave you the clues?
- Aim for 10 minutes.
- You should be able to present most of your solution without reading from your notes. You are, of course, free to reference your notes for calculations, figures, and important points.
- You are not required to have a correct solution to get credit, but you are required to solve all parts of a problem, to make a serious attempt and to "believe" in your solution.
- If you are not prepared you loose all credit for the seminar in question. As long as you have solved the problem yourself, and understood all steps in the solution, this is very unlikely to happen.

As audience you should think of how difficult it is to clearly present a solution. Be humble and supportive. There are multiple ways to solve most problems, so you are encouraged to ask questions. Compare the presentation to your solution and ask questions like "I did it in a different way, is there a difference?" This fosters discussions that are beneficial to everyone in the seminar.<sup>1</sup>

You are of course welcome to take notes.

<sup>&</sup>lt;sup>1</sup>Do not hesitate to ask questions, even if you fear the presenter might not be able to answer. As long as they are able to answer questions about *their approach* and the concepts *they have used*, they run no risk of loosing points for not answering questions from the audience correctly.

Your company has a Linux file server where each division has it's own file area below /home/<division>. Now the main system administrator (you) want to delegate responsibility over users and files in the sales division to an administrator, Maria, in that division. Specifically, she will need right to change owner (chown) and change permissions (chmod) on any files below /home/sales, but not for the rest of the system.

- (a) Suggest how you can achieve the goal above using the protection features available in Linux (file protection, ACL's, capabilities<sup>2</sup>, setuid programs) in the best way possible.
- (b) Discuss your solution according to principle of least privilege and need-to-know. Use in your discussion a worst case example scenario.

#### Problem 2

Two processes need to access the same file. Assume the operating system provides a way for processes to open files with exclusive access. This means that as long as one process has opened a file in exclusive mode, other processes that attempt to open the file need to wait until the first process closes the file. Both processes use this feature.

Further, we assume that processes run on an embedded device where all processes are correctly implemented and no malicious processes exist. When a process in this system tries to open a file that is busy (no matter who opened the file) the operating system will place that process on hold (on a wait queue for the file) until the file is closed.

Process  $J_1$  opens file A for exclusive access after executing for 1 unit of CPU-time from its start. It then keeps it open until it has been executing for an additional 2 units of CPU-time. Process  $J_4$  opens file A for exclusive access after 3 units of CPU-time from its start and closes it after another 2 units of CPU-time.

Job	Priority	Arrival time	Execution time	Open A	Close A
$J_1$	1	6	4	+1	+2
$J_2$	2	6	3	-	-
$J_3$	3	5	6	-	-
$J_4$	4	1	7	+3	+2
$J_5$	5	3	2	-	-

#### Table 1: Job arrivals

- (a) With regard to the above information, show a Gantt chart for the processes in Table 1 running under preemptive priority scheduling. Assume higher priority numbers correspond to lower priorities (so that J1 has higher priority than J5).
- (b) What is meant by turnaround time? Show this for process  $J_1$ .
- (c) Due to its high priority we would expect process  $J_1$  to finish execution after 4 time units, or in worst case after 6 time units if it must wait for exclusive access to the file for the full duration  $J_4$  use the file. What happen in your schedule?
- (d) How can you change the scheduling implementation to fulfill the expectation in previous question?

 $<sup>^2 {\</sup>tt man}$  capabilities

A system uses preemptive priority based scheduling with a time quantum of 10 units. Each process is assigned a number to reflect a relative priority. The higher the number, the higer the priority. For instance, process P1 has higher priority than process P5.

The scheduler uses a priority queue as its ready queue to organize the processes that are ready to execute on the CPU. The priority queue is ordered by priority (highest priority first). The queue is implemented to behave like a FIFO queue for processes with the same priority. This means that processes with the same priority are scheduled in a round-robin fashion with a time quantum of 10 units.

A process may be preempted by a higher priority process even if it did not use all of its time quantum. A preempted process (by a process with a higer priority or at the end of its time quantum) is inserted in the ready queue.

Process	Priority	Burst	Arrival
$P_1$	40	20	0
$P_2$	30	25	25
$P_3$	30	25	30
$P_4$	35	15	60
$P_5$	5	10	100
$P_6$	10	10	105

Table 2: Job data

- (a) Use a Gantt chart to show the scheduling of the processes
- (b) Give the waiting and turnaround times of P3
- (c) Give the CPU utilization in the first 120 time units.

#### Problem 4

Assume a round robin scheduler with time quantum t ms. For the sake of discussion, assume two processes run "forever" and are the only processes to run on the CPU. One of the processes is I/O bound and one is CPU bound. The CPU bound process is always ready to execute. The I/O bound process uses the CPU to process data, but issues a new I/O request after executing on the CPU for 1 ms. Assume each context switch takes 0.2 ms (not included in the time quantum).

- (a) Suppose t is larger than both 1 ms and the time it takes the I/O request to be served. Give the CPU utilization as a function of t.
- (b) Can you improve on the CPU utilization by changing the value of t ? Do you see any drawbacks?

Assume a magnetic hard disk with cylinders numbered from 0 to 3999. The head was positioned at cylinder 100 and is now positioned at cylinder 110. The disk controller is to schedule the following sequence of requests: 75, 1471, 719, 1789, 1024, 1619, 1056, 1851, 120.

- (a) Give the total distance in cylinders to serve all requests for each of the disk scheduling algorithms: First Come First Served (FCFS), Shortest Seek First (SSTF) and Elevator (SCAN).
- (b) Explain advantages/drawbacks (if any) of FCFS compared to SSTF.

## Problem 6

A new hacker, whose code name is Catapault, has an idea to attack your system. They plan to get hold of the free space management for one of the disks in the operating system and randomly change some information therein.

- (a) What kind of serious problems might occur due to the above-mentioned attack scenario? Explain how the hacker could exploit their ability to change the free space manager to 1) read or modify data, and 2) perform a denial of service attack.
- (b) Which free space management scheme (bitmap or linked) do you think is more vulnerable to such attack? Provide appropriate justifications.
- (c) Assume that the OS uses the bitmap scheme for free space management and the attacker is capable of changing only a small portion of the bitmap. Can you think of an efficient mechanism to detect such attacks and/or recover from the same?

Assume that your friend has designed a data structure library, which includes the implementation of **stack** data structure. In particular, the stack data structure keeps track of the last position in the stack and implements routines to insert any element into the stack (**push**) and delete an element from the stack (**pop**). The pseudocode of this two routines appear as follows:

```
push(x) {
    insert "x" into the last position
}
pop() {
    fetch the value from last position and denote it "x"
    remove the last value from the stack and free it's memory
    return "x"
}
```

As you know the threads of a process may be interrupted at any time by an interrupt from hardware (e.g. the timer). The scheduler may then schedule another thread in the process.

If a single process contains two threads that operate on the same stack, the execution may become interleaved. For simplicity, assume that the scheduler only switches between lines in the pseudo-code above (i.e. not in the "middle" of a line).

- (a) Assume that the stack contains the number 5 initially. Further assume that one of the threads executes push(8) and the other executes pop(). List all possible interleavings of the two functions (i.e. different ways in which the line inside push may be executed between lines in pop). Does some of the interleavings produce unexpected results (e.g. either 5 or 8 being overwritten or duplicated)? Explain why.
- (b) Assume that both threads execute pop() and that the stack initially contains 5 and 8 in some order. List all interleavings of the lines in pop(). Does some of them produce unexpected results (e.g. both threads observe that pop() returns 5)? Explain why.

**Hint:** Write each line of pseudo-code on its own post-it note. In how many different sequences can you place the notes? Which of the sequences can occur? (For example, fetch in one thread can not occur after remove in the same thread, the order of execution within one thread can only be the order written in the pseudo-code.) Which sequences will cause inconsistent result? (Compare to the result of calling both functions in a single thread.)

Assume a system with 12-bits virtual addresses. Physical addresses are 16-bits wide. Assume one-level paging with 256-bytes pages. We will consider two processes P1 and P2 with page tables Table 1 and Table 2 respectively. The frame numbers are given in hexadecimal, for instance, 0x10 (in hexadecimal) corresponds to 16 (in decimal). In the tables, the value 1 for the valid bit means the corresponding page entry is in memory and valid. Bits other than the frame number and the valid bit are not relevant for the problem.

- 1. For each one of the following virtual addresses state whether the following virtual addresses are in main memory. If they are, state their equivalent physical address in hexadecimal. All values are given in hexadecimal:
  - (a) Virtual address 0x113 for process P1
  - (b) Virtual address 0x113 for process P2
  - (c) Virtual address 0xCF0 for process P1
  - (d) Virtual address 0xCF0 for process P2
- 2. Do processes P1 and P2 share some frame(s)? If yes, give the virtual addresses of a byte shared by the two processes.

Frame number	Valid bit	Other bits
0x6B	1	XXXXXXX
0x17	1	XXXXXXX
0x60	1	XXXXXXX
0x5B	1	XXXXXXX
0x6A	1	XXXXXXX
0x79	1	XXXXXXX
0x00	0	XXXXXXX
0x6B	0	XXXXXXX
0x97	0	XXXXXXX
0x24	0	XXXXXXX
0x31	0	XXXXXXX
0xA4	0	XXXXXXX
0x72	0	XXXXXXX
0x56	1	XXXXXXX
0x88	0	XXXXXXX
0x1E	0	XXXXXXX
