Network Layer - Control Plane

TDTS04 - Computer Networks and Distributed Systems

Ulf Kargén

Division for Database and Information Techniques (ADIT)
Department of Computer and Information Science (IDA)

Network layer control plane: our goals

- •understand principles behind network control plane:
 - traditional routing algorithms
 - SDN controllers
 - network management, configuration

- instantiation, implementation in the Internet:
 - OSPF, BGP
 - OpenFlow, ODL and ONOS controllers
 - Internet Control Message
 Protocol: ICMP
 - SNMP, YANG/NETCONF

Network layer: "control plane" roadmap

- introduction
- routing protocols
 - link state
 - distance vector
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control Message Protocol

Network-layer functions

- forwarding: move packets from router's input to appropriate router output
 - routing: determine route taken by packets from source to destination

data plane

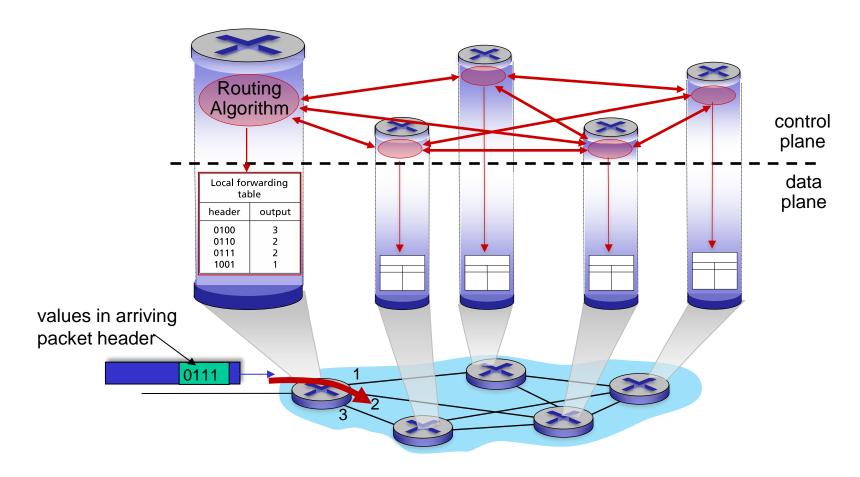

control plane

Two approaches to structuring network control plane:

- per-router control (traditional)
- logically centralized control (software defined networking)

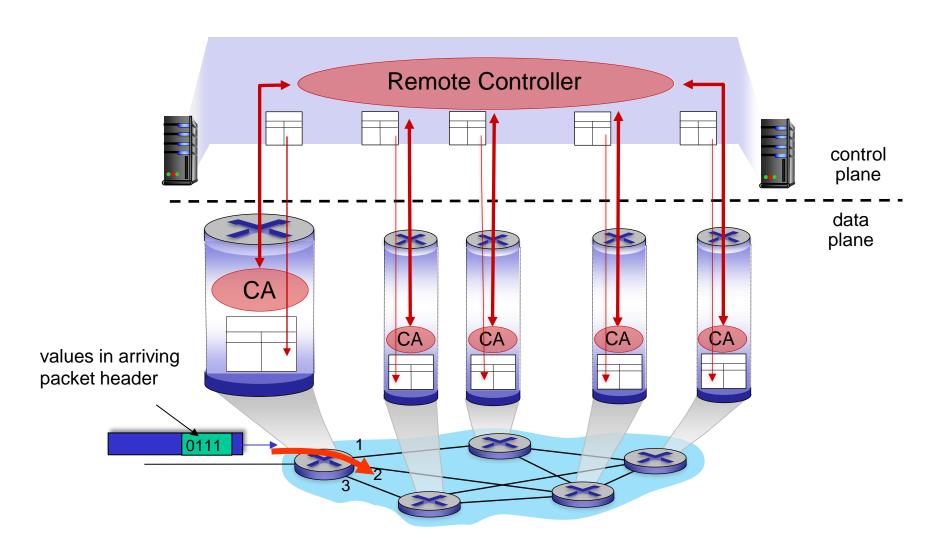

Per-router control plane

Individual routing algorithm components in each and every router interact in the control plane

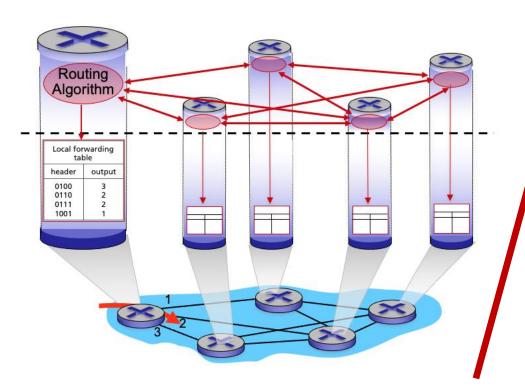

Software-Defined Networking (SDN) control plane

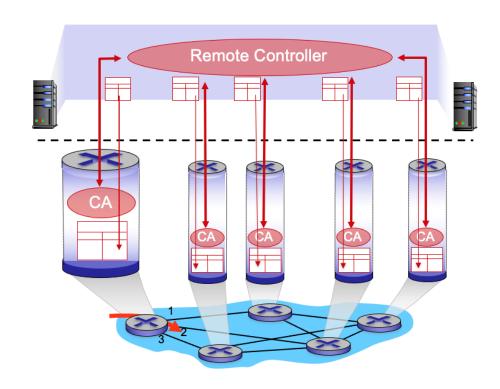

Remote controller computes, installs forwarding tables in routers

Per-router control plane

SDN control plane

Network layer: "control plane" roadmap

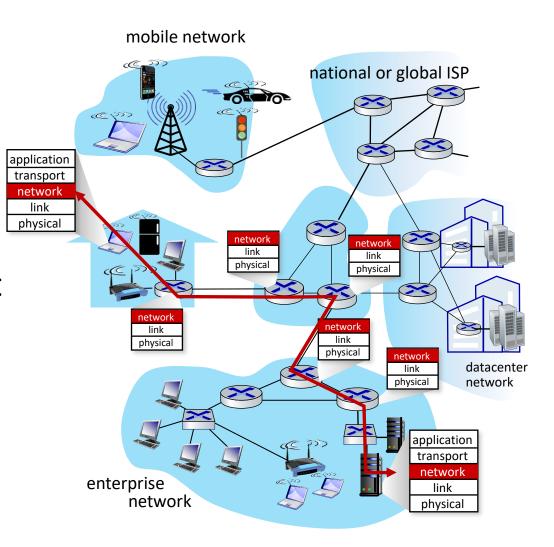

- introduction
- routing protocols
 - link state
 - distance vector
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control Message Protocol

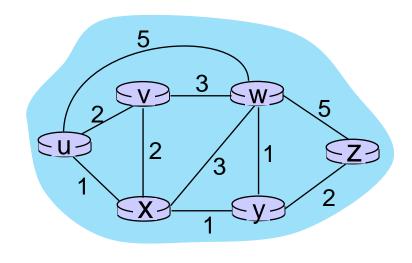

Routing protocols

Routing protocol goal: determine "good" paths (equivalently, routes), from sending hosts to receiving host, through network of routers

- path: sequence of routers packets traverse from given initial source host to final destination host
- "good": least "cost", "fastest", "least congested"
- routing: a "top-10" networking challenge!

Graph abstraction: link costs

 $c_{a,b}$: cost of *direct* link connecting a and b $e.g., c_{w,z} = 5, c_{u,z} = \infty$

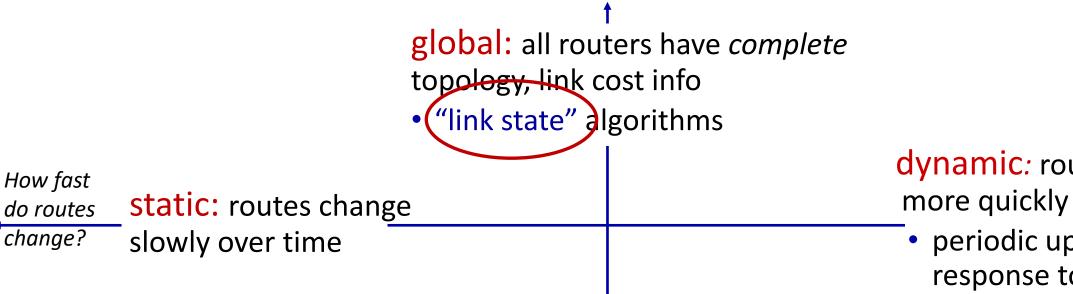

cost defined by network operator: could always be 1, or inversely related to bandwidth, or inversely related to congestion

graph: G = (N, E)

N: set of routers = $\{u, v, w, x, y, z\}$

E: set of links = { (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) }

Routing algorithm classification

dynamic: routes change

 periodic updates or in response to link cost changes

decentralized: iterative process of computation, exchange of info with neighbors

- routers initially only know link costs to attached neighbors
- ("distance vector") algorithms

global or decentralized information?

Network layer: "control plane" roadmap

- introduction
- routing protocols
 - link state
 - distance vector
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

Dijkstra's link-state routing algorithm

- centralized: network topology, link costs known to all nodes
 - accomplished via "link state broadcast"
 - all nodes have same info
- computes least cost paths from one node ("source") to all other nodes
 - gives *forwarding table* for that node
- iterative: after k iterations, know least cost path to k destinations

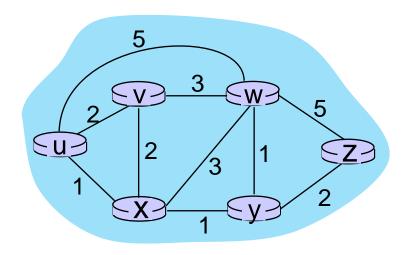

notation

- $c_{x,y}$: direct link cost from node x to y; = ∞ if not direct neighbors
- D(v): current estimate of cost of least-cost-path from source to destination v
- p(v): predecessor node along path from source to v
- N': set of nodes whose leastcost-path definitively known

Dijkstra's link-state routing algorithm

```
1 Initialization:
   N' = \{u\}
                                 /* compute least cost path from u to all other nodes */
   for all nodes v
     if v adjacent to u
                                 /* u initially knows direct-path-cost only to direct neighbors
       then D(v) = c_{u,v}
                                                                                          */
                                 /* but may not be minimum cost!
    else D(v) = \infty
   Loop
     find w not in N' such that D(w) is a minimum
     add w to N'
     update D(v) for all v adjacent to w and not in N':
         D(v) = \min \left( D(v), D(w) + c_{w,v} \right)
     /* new least-path-cost to v is either old least-cost-path to v or known
      least-cost-path to w plus direct-cost from w to v */
15 until all nodes in N'
```

5	uxyvwz					
			8 Loor	\setminus		

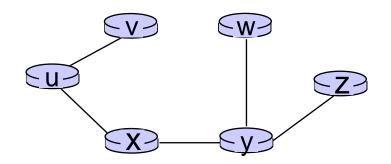

- find a not in N' such that D(a) is a minimum
- add a to N' 10
- update D(b) for all b adjacent to a and not in N':

Now we can deduce that the optimal path to z is $U \rightarrow X \rightarrow Y \rightarrow Z$

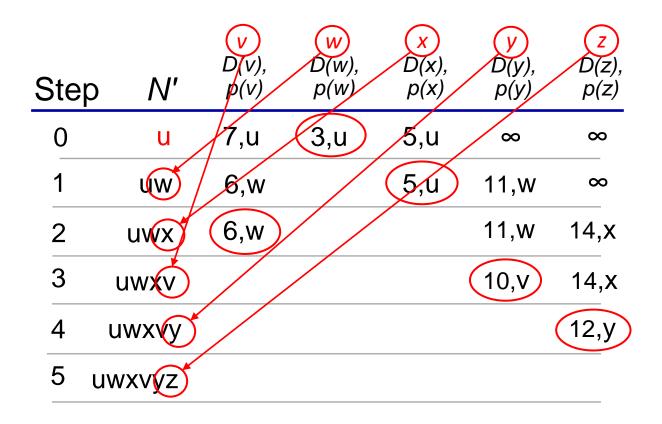

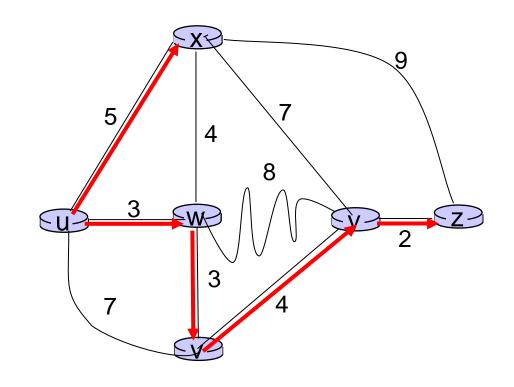

resulting least-cost-path tree from u:

resulting forwarding table in u:

destination	outgoing link	
V	(u,v) —	route from <i>u</i> to <i>v</i> directly
X	(u,x)	
У	(u,x)	route from u to all
W	(u,x)	other destinations
X	(u,x)	via <i>x</i>

notes:

- construct least-cost-path tree by tracing predecessor nodes
- ties can exist (can be broken arbitrarily)

Dijkstra's algorithm: discussion

algorithm complexity: *n* nodes

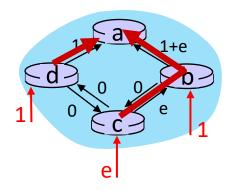

- each of n iteration: need to check all nodes, w, not in N
- n(n+1)/2 comparisons: $O(n^2)$ complexity
- more efficient implementations possible: O(nlogn)

message complexity:

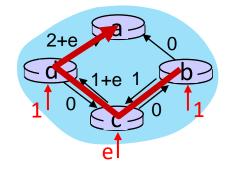

- each router must broadcast its link state information (direct neighbor costs) to other n routers
- efficient (and interesting!) broadcast algorithms: O(n) link crossings to disseminate a broadcast message from one source
- each router's message crosses O(n) links: overall message complexity: $O(n^2)$

Dijkstra's algorithm: oscillations possible

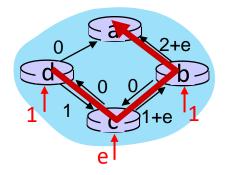

- when link costs depend on traffic volume, route oscillations possible
- sample scenario:
 - routing to destination a, traffic entering at d, c, b with rates 1, e (<1), 1
 - link costs are directional, and volume-dependent

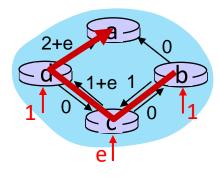

initially

given these costs, find new routing.... resulting in new costs

given these costs, find new routing.... resulting in new costs

given these costs, find new routing.... resulting in new costs

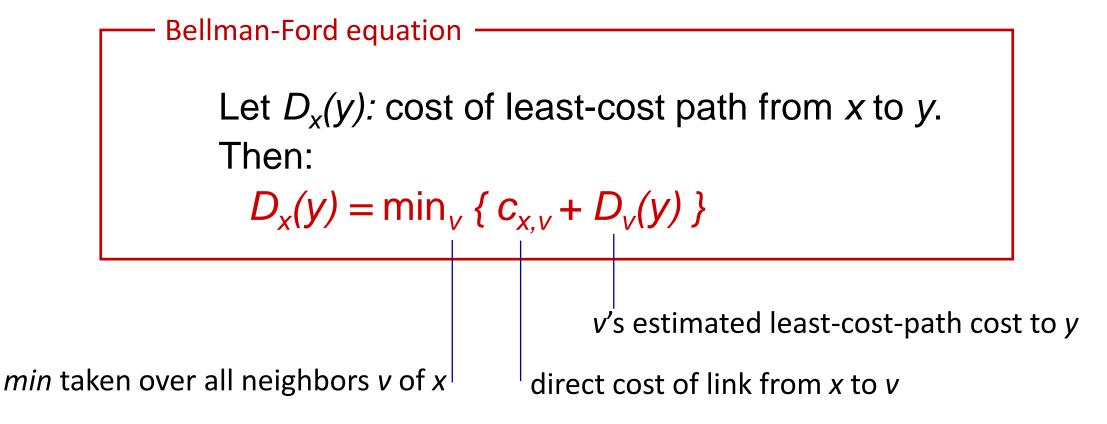

Network layer: "control plane" roadmap

- introduction
- routing protocols
 - link state
 - distance vector
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

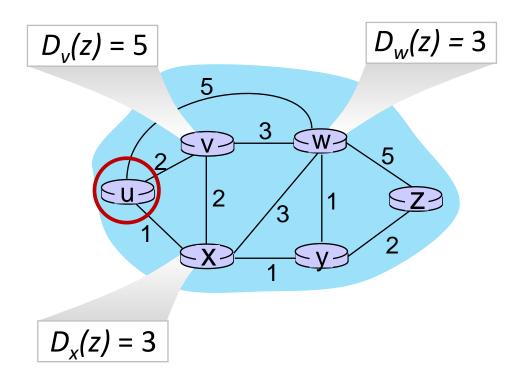

Distance vector algorithm

Based on *Bellman-Ford* (BF) equation (dynamic programming):

Bellman-Ford Example

Suppose that u's neighboring nodes, x,v,w, know that for destination z:

Bellman-Ford equation says:

$$D_{u}(z) = \min \{ c_{u,v} + D_{v}(z), c_{u,x} + D_{x}(z), c_{u,w} + D_{w}(z) \}$$

$$= \min \{ 2 + 5, 1 + 3, 5 + 3 \} = 4$$

node achieving minimum (x) is next hop on estimated leastcost path to destination (z)

Distance vector algorithm

key idea:

- from time-to-time, each node sends its own distance vector estimate to neighbors
- when x receives new DV estimate from any neighbor, it updates its own DV using B-F equation:

$$D_x(y) \leftarrow \min_{v} \{c_{x,v} + D_v(y)\}$$
 for each node $y \in N$

• under minor, natural conditions, the estimate $D_x(y)$ converge to the actual least cost $d_x(y)$

Distance vector algorithm:

each node:

wait for (change in local link cost or msg from neighbor)

recompute DV estimates using DV received from neighbor

if DV to any destination has changed, *notify* neighbors

iterative, asynchronous: each local iteration caused by:

- local link cost change
- DV update message from neighbor

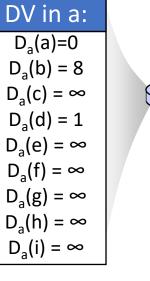

distributed, self-stopping: each node notifies neighbors *only* when its DV changes

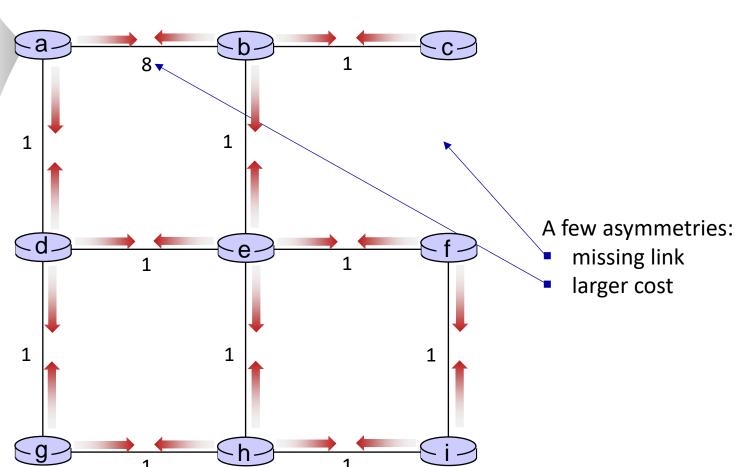

- neighbors then notify their neighbors – only if necessary
- no notification received, no actions taken!

Distance vector: example

- All nodes have distance estimates to nearest neighbors (only)
- All nodes send their local distance vector to their neighbors

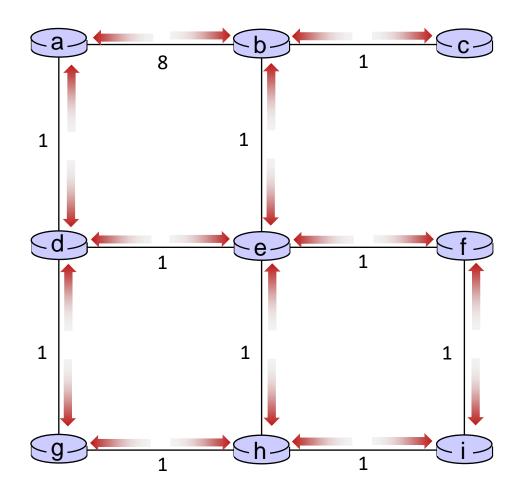

Distance vector example: iteration

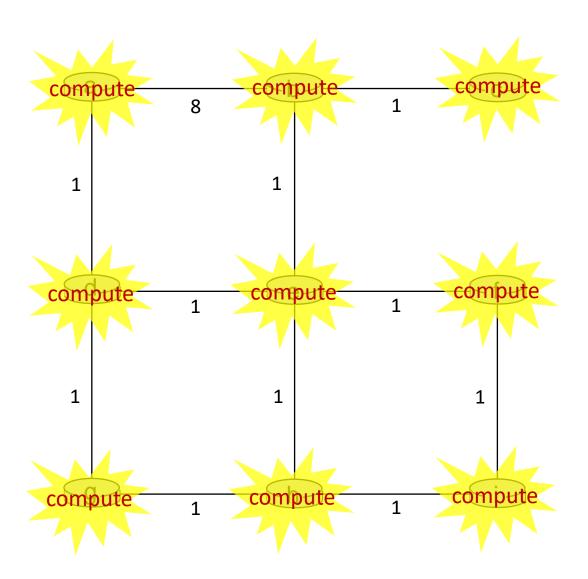

All nodes:

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

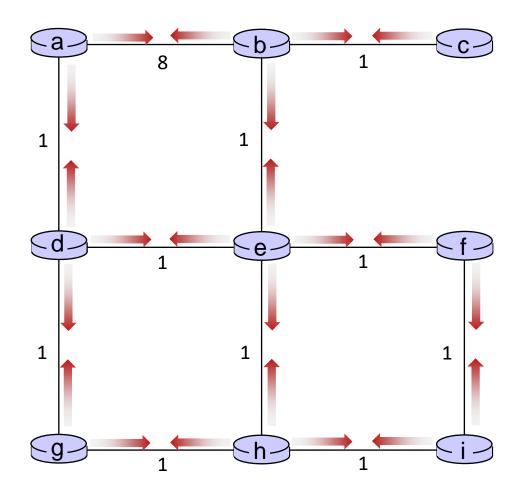

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

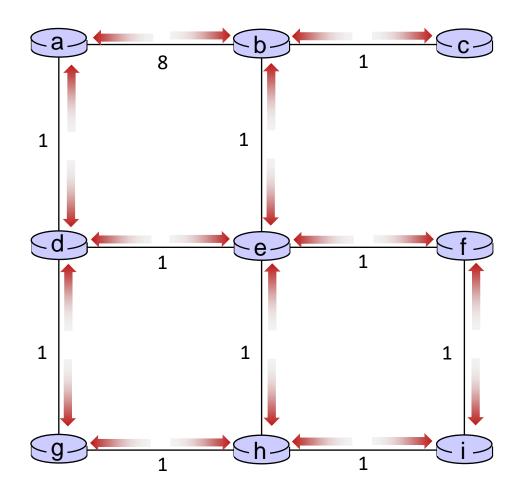

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

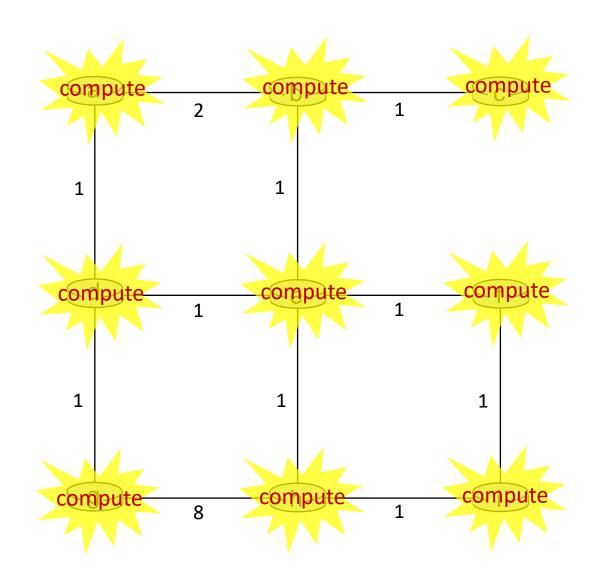

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

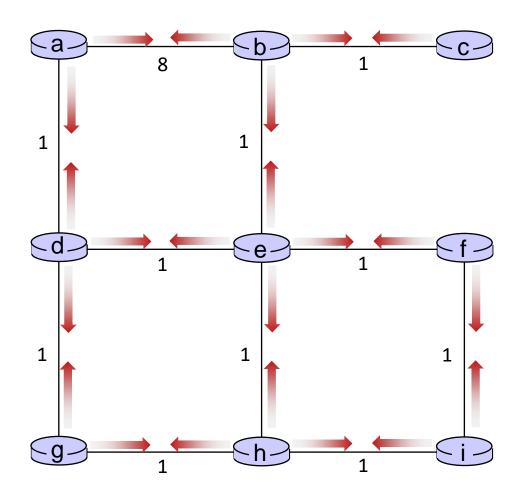

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

.... and so on

Let's next take a look at the iterative computations at nodes

$$D_c(b) = \infty$$

$$D^{c}(c) = \infty$$

$$D_c(d) = 0$$

$$D_{c}(e) = 1$$

$$D_c(f) = \infty$$

$$D_{c}(g) = 1$$

$$D_c(h) = \infty$$

$$D_c(i) = \infty$$

$D_c(h) = \infty$ $D_c(i) = \infty$

DV in h:

$$D_c(a) = \infty$$

$$D_c(b) = \infty$$

$$D_c(c) = \infty$$

$$D_c(d) = \infty$$

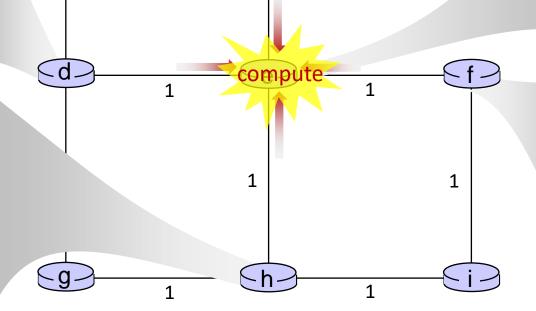

$$D_{c}(e) = 1$$

$$D_c(f) = \infty$$

$$D_c(g) = 1$$

$$D_c(h) = 0$$

$$D_c(i) = 1$$

Q: what is new DV computed in e at

t=1?

DV in f:

$$D_c(a) = \infty$$

$$D_c(b) = \infty$$

$$D_c(c) = \infty$$

$$D_c(d) = \infty$$

$$D_{c}(e) = 1$$

$$D_c(f)=0$$

$$D_c(g) = \infty$$

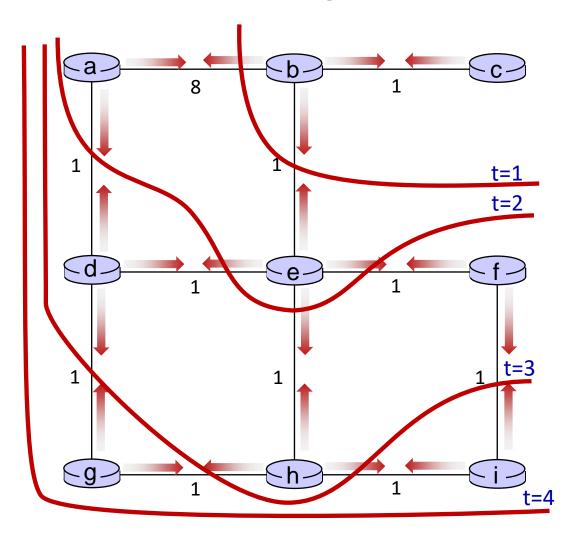

$$D_c(h) = \infty$$

$$D_c(i) = 1$$

Distance vector: state information diffusion

Iterative communication, computation steps diffuses information through network:

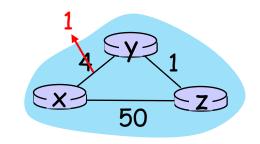

- t=0 c's state at t=0 is at c only
- c's state at t=0 has propagated to b, and may influence distance vector computations up to **1** hop away, i.e., at b
- c's state at t=0 may now influence distance vector computations up to 2 hops away, i.e., at b and now at a, e as well
- c's state at t=0 may influence distance vector computations up to **3** hops away, i.e., at d, f, h
- c's state at t=0 may influence distance vector computations up to 4 hops away, i.e., at g, i

Distance vector: link cost changes

link cost changes:

- node detects local link cost change
- updates routing info, recalculates local DV
- if DV changes, notify neighbors

"good news travels fast"

 t_0 : y detects link-cost change, updates its DV, informs its neighbors.

 t_1 : z receives update from y, updates its DV, computes new least cost to x, sends its neighbors its DV.

 t_2 : y receives z's update, updates its DV. y's least costs do not change, so y does not send a message to z.

Distance vector: link cost changes

link cost changes:

- node detects local link cost change
- "bad news travels slow" count-to-infinity problem:

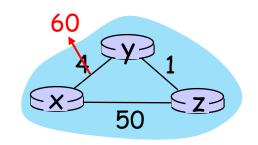

- y sees direct link to x has new cost 60, but z has said it has a path at cost of 5. So y computes "my new cost to x will be 6, via z); notifies z of new cost of 6 to x.
- z learns that path to x via y has new cost 6, so z computes "my new cost to x will be 7 via y), notifies y of new cost of 7 to x.
- y learns that path to x via z has new cost 7, so y computes "my new cost to x will be 8 via y), notifies z of new cost of 8 to x.
- z learns that path to x via y has new cost 8, so z computes "my new cost to x will be 9 via y), notifies y of new cost of 9 to x.

• • •

• see text for solutions. *Distributed algorithms are tricky!*

Poisoned Reverse

Trick to avoid count-to-infinity problem (in simple cases):

- Problem arises because y cannot know that z's supposed low-cost path actually goes through y itself
- Poisoned reverse:

if z currently routes through y to get to destination x (i.e., this is the lowest-cost path from z to x) then z will (falsely) advertise to y that $D_z(x) = \infty$

- Note: not a silver bullet!
 - Loops with more nodes can still lead to the count-to-infinity problem

Comparison of LS and DV algorithms

message complexity

LS: n routers, $O(n^2)$ messages sent

DV: exchange between neighbors; convergence time varies

speed of convergence

LS: $O(n^2)$ algorithm, $O(n^2)$ messages

may have oscillations

DV: convergence time varies

- may have routing loops
- count-to-infinity problem

robustness: what happens if router malfunctions, or is compromised?

LS:

- router can advertise incorrect link cost
- each router computes only its own table

DV:

- DV router can advertise incorrect path cost ("I have a really low-cost path to everywhere"): black-holing
- each router's DV is used by others: error propagate thru network

Network layer: "control plane" roadmap

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

Making routing scalable

our routing study thus far - idealized

- all routers identical
- network "flat"
- ... not true in practice

scale: billions of destinations:

- can't store all destinations in routing tables!
- routing table exchange would swamp links!

administrative autonomy:

- Internet: a network of networks
- each network admin may want to control routing in its own network

Internet approach to scalable routing

aggregate routers into regions known as "autonomous systems" (AS) (a.k.a. "domains")

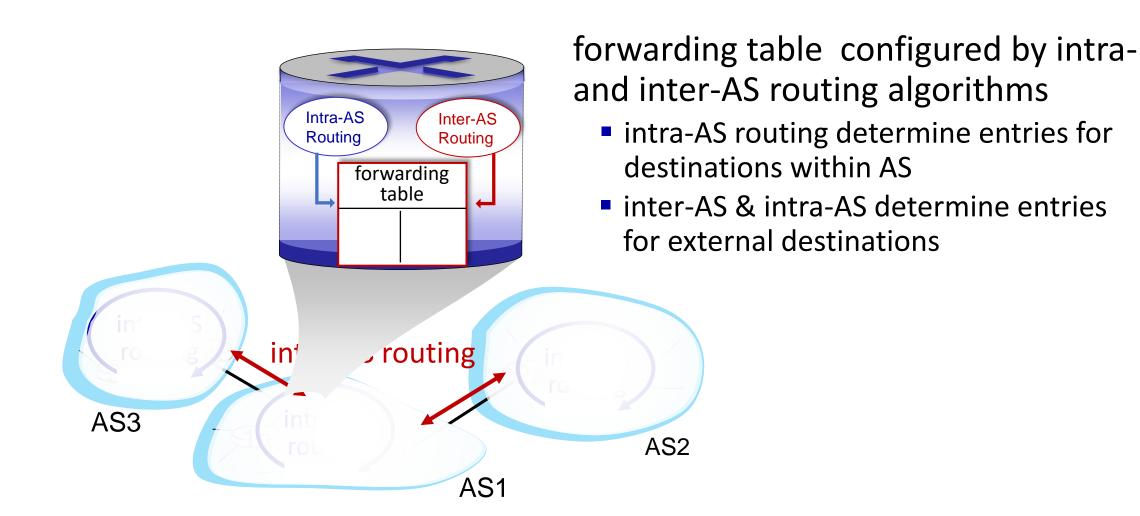

intra-AS (aka "intra-domain"): routing among routers within same AS ("network")

- all routers in AS must run same intradomain protocol
- routers in different AS can run different intra-domain routing protocols
- gateway router: at "edge" of its own AS, has link(s) to router(s) in other AS'es

inter-AS (aka "inter-domain"): routing *among* AS'es

 gateways perform inter-domain routing (as well as intra-domain routing)

Interconnected ASes

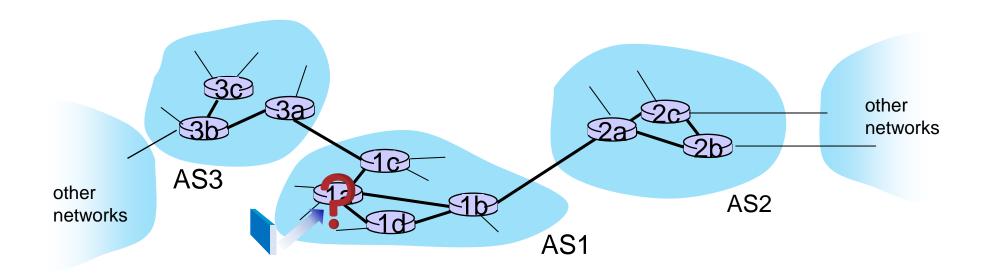

Inter-AS routing: a role in intradomain forwarding

- suppose router in AS1 receives datagram destined outside of AS1:
- router should forward packet to gateway router in AS1, but which one?

AS1 inter-domain routing must:

- 1. learn which destinations reachable through AS2, which through AS3
- 2. propagate this reachability info to all routers in AS1

Intra-AS routing: routing within an AS

most common intra-AS routing protocols:

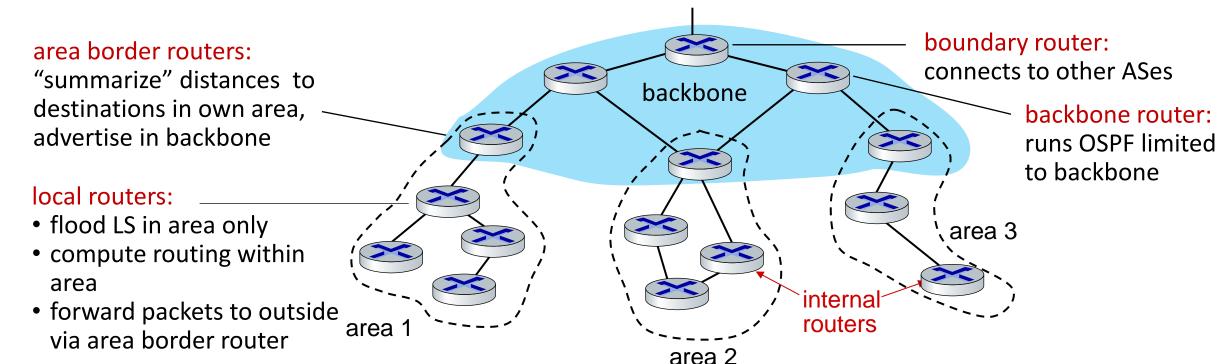

- RIP: Routing Information Protocol [RFC 1723]
 - classic DV: DVs exchanged every 30 secs
 - no longer widely used
- EIGRP: Enhanced Interior Gateway Routing Protocol
 - DV based
 - formerly Cisco-proprietary for decades (became open in 2013 [RFC 7868])
- OSPF: Open Shortest Path First [RFC 2328]
 - link-state routing
 - IS-IS protocol (ISO standard, not RFC standard) essentially same as OSPF

OSPF (Open Shortest Path First) routing

- "open": publicly available
- classic link-state
 - each router floods OSPF link-state advertisements (directly over IP rather than using TCP/UDP) to all other routers in entire AS
 - multiple link costs metrics possible: bandwidth, delay
 - each router has full topology, uses Dijkstra's algorithm to compute forwarding table
 - security: all OSPF messages authenticated (to prevent malicious intrusion)

Hierarchical OSPF

- two-level hierarchy: local area, backbone.
 - link-state advertisements flooded only in area, or backbone
 - each node has detailed area topology; only knows direction to reach other destinations

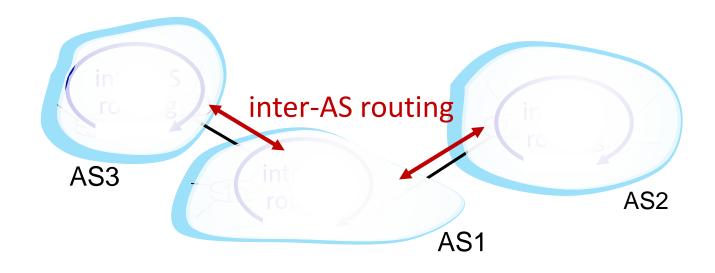

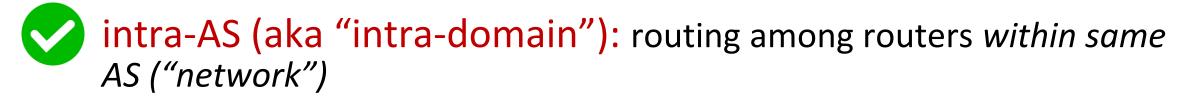

Network layer: "control plane" roadmap

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

Interconnected ASes

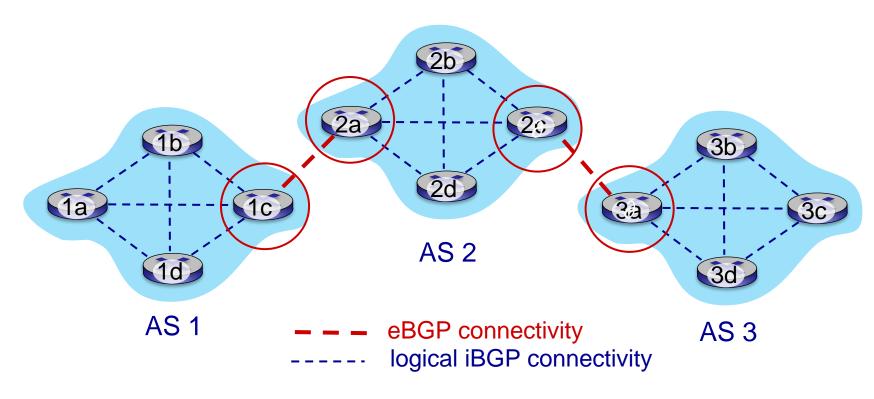

inter-AS (aka "inter-domain"): routing among AS'es

Internet inter-AS routing: BGP

- BGP (Border Gateway Protocol): the de facto inter-domain routing protocol
 - "glue that holds the Internet together"
- allows subnet to advertise its existence, and the destinations it can reach, to rest of Internet: "I am here, here is who I can reach, and how"
- BGP provides each AS a means to:
 - obtain destination network reachability info from neighboring ASes (eBGP)
 - determine routes to other networks based on reachability information and policy
 - propagate reachability information to all AS-internal routers (iBGP)
 - advertise (to neighboring networks) destination reachability info

eBGP, iBGP connections

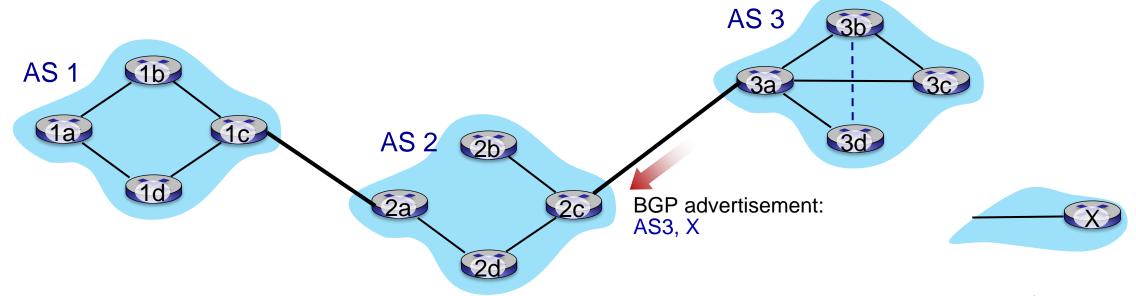

gateway routers run both eBGP and iBGP protocols

BGP basics

- BGP session: two BGP routers ("peers") exchange BGP messages over semi-permanent TCP connection:
 - advertising paths to different destination network prefixes (BGP is a "path vector" protocol)
- when AS3 gateway 3a advertises path AS3,X to AS2 gateway 2c:
 - AS3 promises to AS2 it will forward datagrams towards X

BGP protocol messages

- BGP messages exchanged between peers over TCP connection
- BGP messages [RFC 4371]:
 - OPEN: opens TCP connection to remote BGP peer and authenticates sending BGP peer
 - UPDATE: advertises new path (or withdraws old)
 - KEEPALIVE: keeps connection alive in absence of UPDATES; also ACKs
 OPEN request
 - NOTIFICATION: reports errors in previous msg; also used to close connection

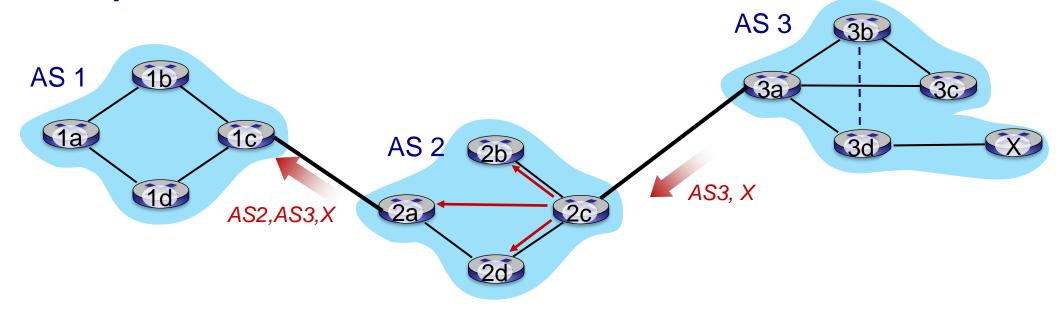

Path attributes and BGP routes

- BGP advertised route: prefix + attributes
 - prefix: destination being advertised
 - two important attributes:
 - AS-PATH: list of ASes through which prefix advertisement has passed
 - NEXT-HOP: indicates specific internal-AS router to next-hop AS

policy-based routing:

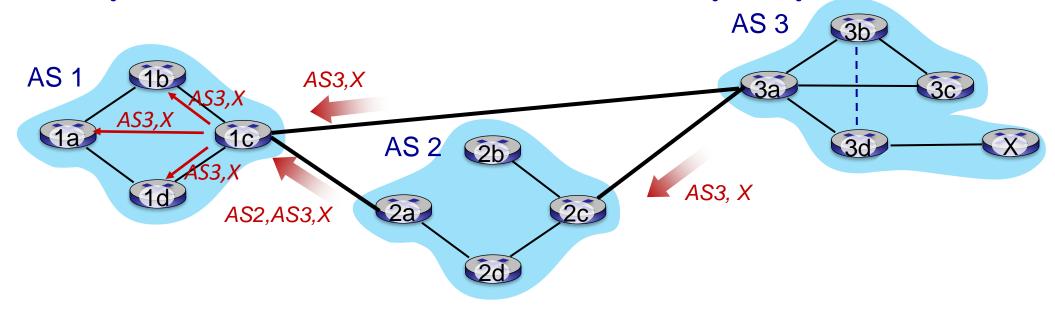

- gateway receiving route advertisement uses *import policy* to accept/decline path (e.g., never route through AS Y).
- AS policy also determines whether to advertise path to other other neighboring Ases
- For example: "We have business agreement with AS X, so prefer them", "Routing through AS Y beneficial for our competitor, so never do that"

BGP path advertisement

- AS2 router 2c receives path advertisement AS3,X (via eBGP) from AS3 router 3a
- based on AS2 policy, AS2 router 2c accepts path AS3,X, propagates (via iBGP) to all AS2 routers
- based on AS2 policy, AS2 router 2a advertises (via eBGP) path AS2, AS3, X to AS1 router 1c

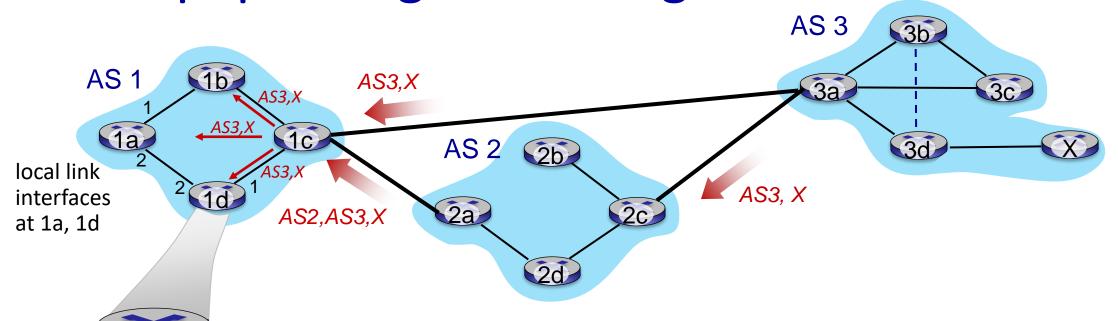

BGP path advertisement: multiple paths

gateway router may learn about multiple paths to destination:

- AS1 gateway router 1c learns path AS2, AS3, X from 2a
- AS1 gateway router 1c learns path AS3,X from 3a
- based on policy, AS1 gateway router 1c chooses path AS3,X and advertises path within AS1 via iBGP

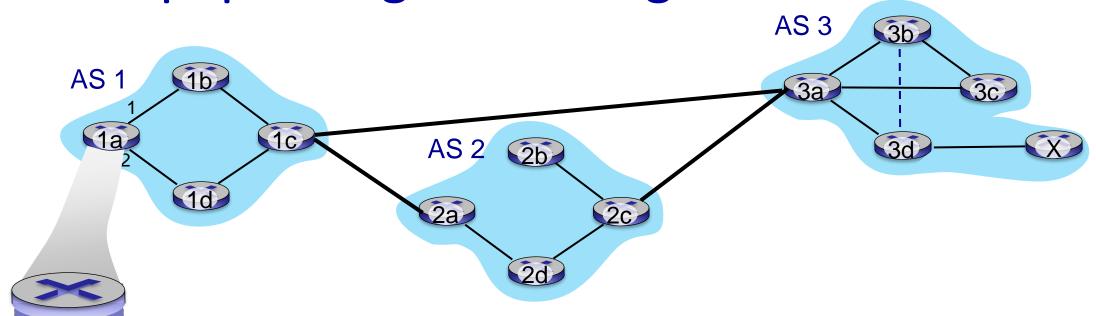

BGP: populating forwarding tables

dest	interface
1c	1
X	1
•••	•••

- recall: 1a, 1b, 1d learn via iBGP from 1c: "path to X goes through 1c"
- at 1d: OSPF intra-domain routing: to get to 1c, use interface 1
- at 1d: to get to X, use interface 1

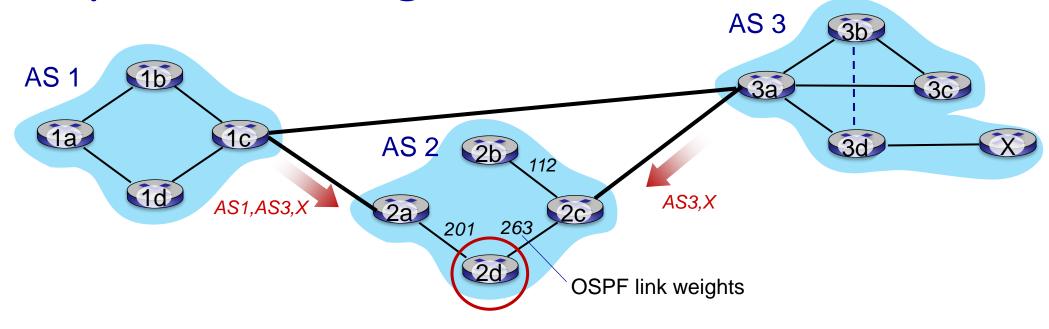

BGP: populating forwarding tables

dest	interface
1	 2
1c X	2

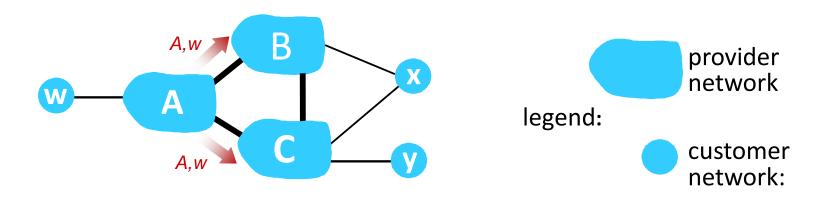

- recall: 1a, 1b, 1d learn via iBGP from 1c: "path to X goes through 1c"
- at 1d: OSPF intra-domain routing: to get to 1c, use interface 1
- at 1d: to get to X, use interface 1
- at 1a: OSPF intra-domain routing: to get to 1c, use interface 2
- at 1a: to get to X, use interface 2

Hot potato routing

- 2d learns (via iBGP) it can route to X via 2a or 2c
- hot potato routing: choose local gateway that has least intra-domain cost (e.g., 2d chooses 2a, even though more AS hops to X): don't worry about inter-domain cost!

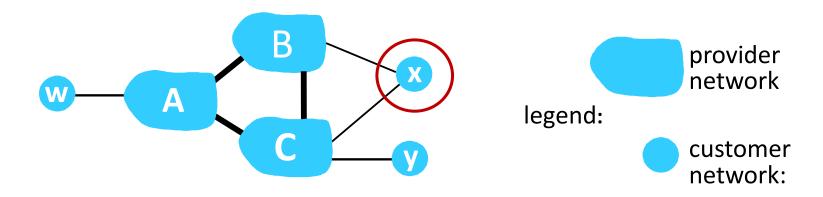

BGP: achieving policy via advertisements

ISP only wants to route traffic to/from its customer networks (does not want to carry transit traffic between other ISPs – a typical "real world" policy)

- A advertises path Aw to B and to C
- B chooses not to advertise BAw to C!
 - B gets no "revenue" for routing CBAw, since none of C, A, w are B's customers
 - C does not learn about CBAw path
- C will route CAw (not using B) to get to w

BGP: achieving policy via advertisements (more)

ISP only wants to route traffic to/from its customer networks (does not want to carry transit traffic between other ISPs – a typical "real world" policy)

- A,B,C are provider networks
- x,w,y are customer (of provider networks)
- x is dual-homed: attached to two networks
- policy to enforce: x does not want to route from B to C via x
 - .. so x will not advertise to B a route to C

BGP route selection

- router may learn about more than one route to destination AS, selects route based on:
 - 1. local preference value attribute: policy decision
 - 2. shortest AS-PATH
 - 3. closest NEXT-HOP router: hot potato routing
 - 4. additional criteria

Why different Intra-, Inter-AS routing?

policy:

- inter-AS: admin wants control over how its traffic routed, who routes through its network
- intra-AS: single admin, so policy less of an issue

scale:

hierarchical routing saves table size, reduced update traffic

performance:

- intra-AS: can focus on performance
- inter-AS: policy dominates over performance

Network layer: "control plane" roadmap

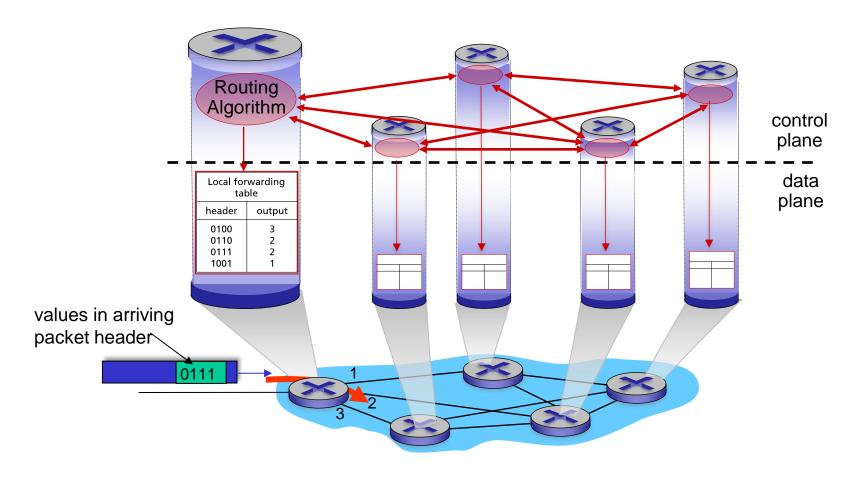

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control MessageProtocol

- Internet network layer: historically implemented via distributed, per-router control approach:
 - monolithic router contains switching hardware, runs proprietary implementation of Internet standard protocols (IP, RIP, IS-IS, OSPF, BGP) in proprietary router OS (e.g., Cisco IOS)
 - different "middleboxes" for different network layer functions: firewalls, load balancers, NAT boxes, ..
- ~2005: renewed interest in rethinking network control plane

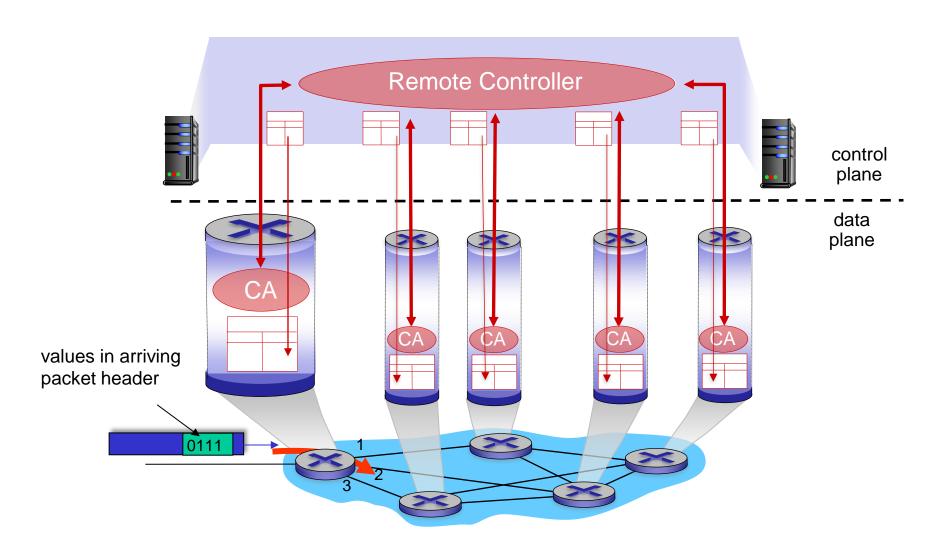

Per-router control plane

Individual routing algorithm components in each and every router interact in the control plane to compute forwarding tables

Software-Defined Networking (SDN) control plane

Remote controller computes, installs forwarding tables in routers

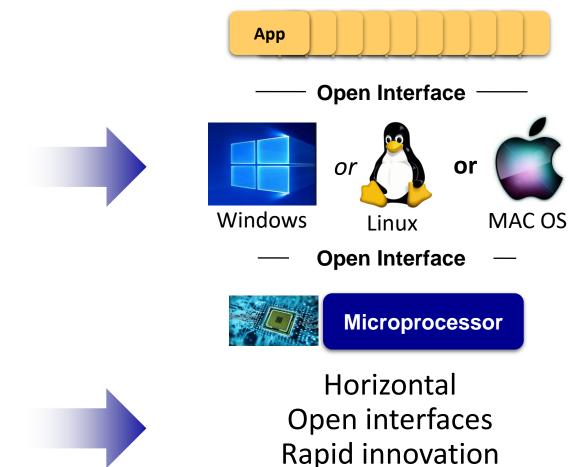

Why a logically centralized control plane?

- easier network management: avoid router misconfigurations, greater flexibility of traffic flows
- table-based forwarding (recall OpenFlow API) allows "programming" routers
 - centralized "programming" easier: compute tables centrally and distribute
 - distributed "programming" more difficult: compute tables as result of distributed algorithm (protocol) implemented in each-and-every router
- open (non-proprietary) implementation of control plane
 - foster innovation: let 1000 flowers bloom

SDN analogy: mainframe to PC revolution

Network Layer: 5-84

Traffic engineering: difficult with traditional routing

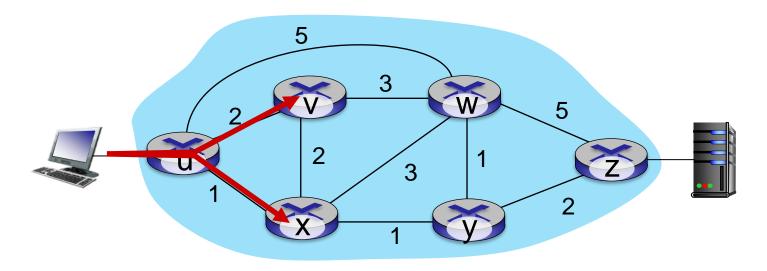

<u>Q:</u> what if network operator wants u-to-z traffic to flow along uvwz, rather than uxyz?

<u>A:</u> need to re-define link weights so traffic routing algorithm computes routes accordingly (or need a new routing algorithm)!

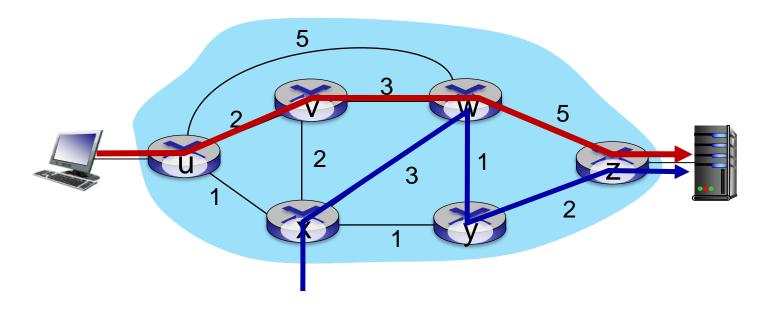

link weights are only control "knobs": not much control!

Traffic engineering: difficult with traditional routing

<u>Q:</u> what if network operator wants to split u-to-z traffic along uvwz <u>and</u> uxyz (load balancing)? <u>A:</u> can't do it (or need a new routing algorithm)

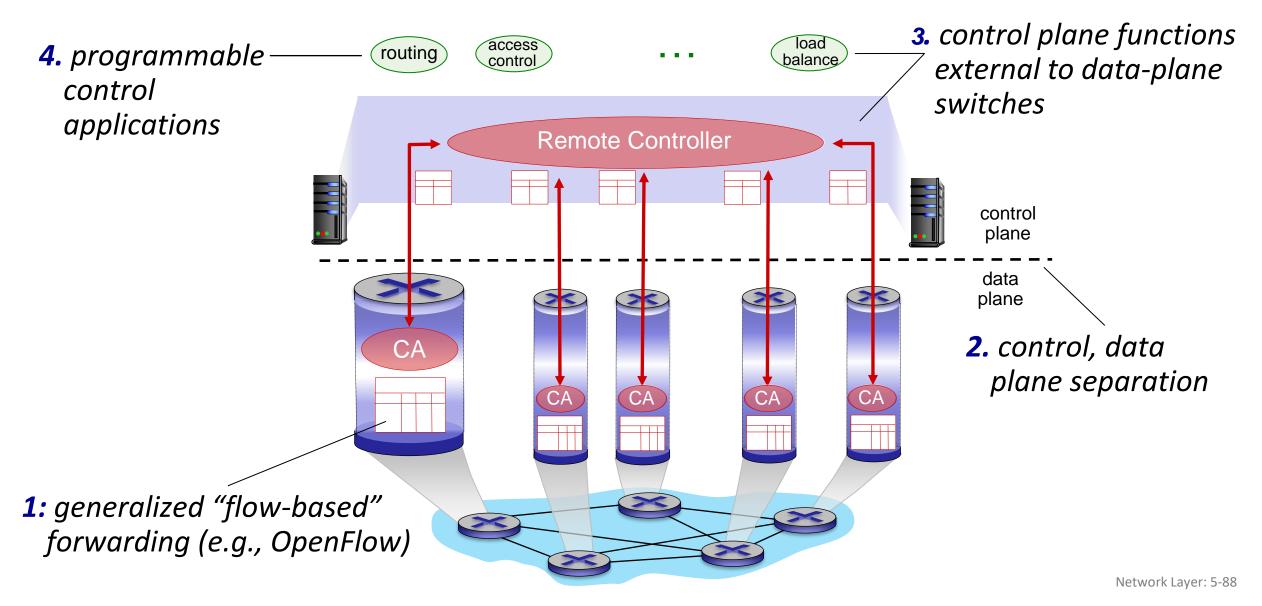

Traffic engineering: difficult with traditional routing

<u>Q:</u> what if w wants to route blue and red traffic differently from w to z?

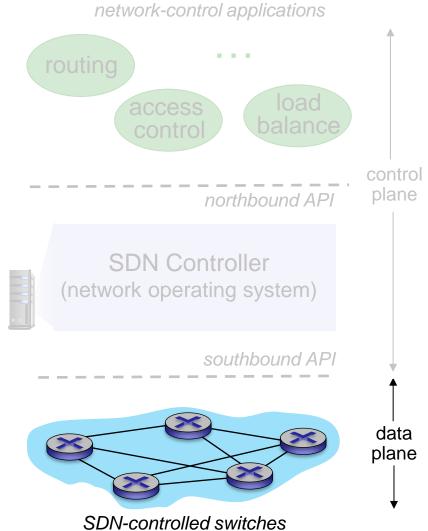

A: can't do it (with destination-based forwarding, and LS, DV routing)

We learned in Chapter 4 that generalized forwarding and SDN can be used to achieve *any* routing desired

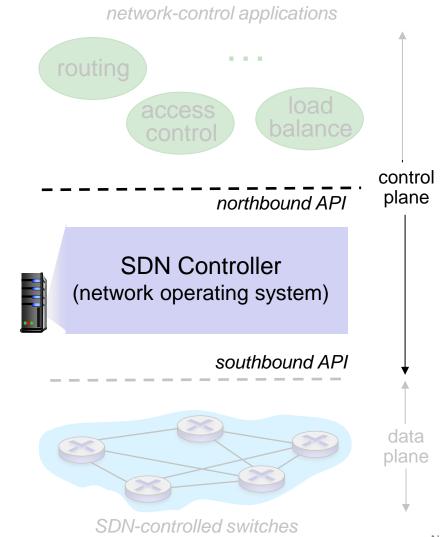

Data-plane switches:

- fast, simple, commodity switches implementing generalized data-plane forwarding (Section 4.4) in hardware
- flow (forwarding) table computed, installed under controller supervision
- API for table-based switch control (e.g., OpenFlow)
 - defines what is controllable, what is not
- protocol for communicating with controller (e.g., OpenFlow)

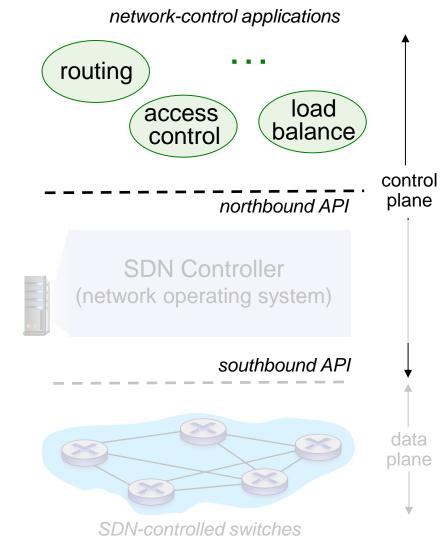

SDN controller (network OS):

- maintain network state information
- interacts with network control applications "above" via northbound API
- interacts with network switches "below" via southbound API
- implemented as distributed system for performance, scalability, faulttolerance, robustness

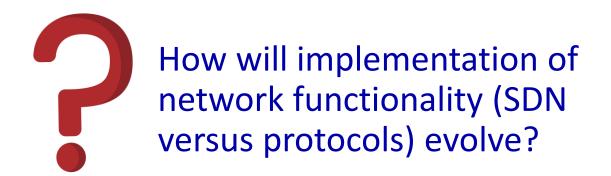

network-control apps:

- "brains" of control: implement control functions using lower-level services, API provided by SDN controller
- unbundled: can be provided by 3rd party: distinct from routing vendor, or SDN controller

SDN and the future of traditional network protocols

- SDN-computed versus router-computer forwarding tables:
 - just one example of logically-centralized-computed versus protocol computed
- one could imagine SDN-computed congestion control:
 - controller sets sender rates based on router-reported (to controller) congestion levels

Network layer: "control plane" roadmap

- introduction
- routing protocols
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control Message Protocol

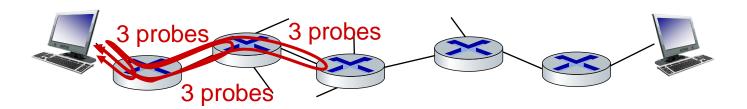

ICMP: internet control message protocol

- used by hosts and routers to communicate network-level information
 - error reporting: unreachable host, network, port, protocol
 - echo request/reply (used by ping)
- network-layer "above" IP:
 - ICMP messages carried in IP datagrams
- ICMP message: type, code plus first 8 bytes of IP datagram causing error

<u>Type</u>	<u>Code</u>	<u>description</u>
0	0	echo reply (ping)
3	0	dest. network unreachable
3	1	dest host unreachable
3	2	dest protocol unreachable
3	3	dest port unreachable
3	6	dest network unknown
3	7	dest host unknown
4	0	source quench (congestion
		control - not used)
8	0	echo request (ping)
9	0	route advertisement
10	0	router discovery
11	0	TTL expired
12	0	bad IP header

Traceroute and ICMP

- source sends sets of UDP segments to destination
 - 1st set has TTL =1, 2nd set has TTL=2, etc.
- datagram in *n*th set arrives to nth router:
 - router discards datagram and sends source ICMP message (type 11, code 0)
 - ICMP message possibly includes name of router & IP address
- when ICMP message arrives at source: record RTTs

stopping criteria:

- UDP segment eventually arrives at destination host
- destination returns ICMP "port unreachable" message (type 3, code 3)
- source stops

Network layer: Summary

we've learned a lot!

- approaches to network control plane
 - per-router control (traditional)
 - logically centralized control (software defined networking)
- traditional routing algorithms
 - implementation in Internet: OSPF, BGP
- SDN controllers
 - implementation in practice: ODL, ONOS
- Internet Control Message Protocol
- network management

next stop: link layer!

Network layer, control plane: Done!

- introduction
- routing protocols
 - link state
 - distance vector
- intra-ISP routing: OSPF
- routing among ISPs: BGP
- SDN control plane
- Internet Control Message Protocol
