

# DISCRETE EVENT MODELS

- 1. What Is a Discrete Event Model?**
- 2. Discrete Event Simulation**
- 3. Efficiency of Discrete Event Simulation**
- 4. Potential Ambiguities in Discrete Event Simulation**

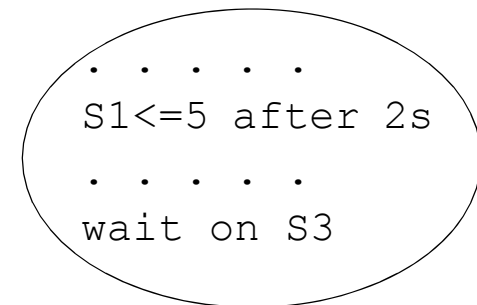

# Discrete Event Models

- The system is a collection of processes that respond to events.
- *Each event carries a time-stamp indicating the time at which the event occurs.*
- *Time-stamps are totally ordered.*
- A Discrete Event (DE) simulator maintains a *global event queue sorted by the time-stamps*. The simulator also keeps a single global time.

# Discrete Event Simulator

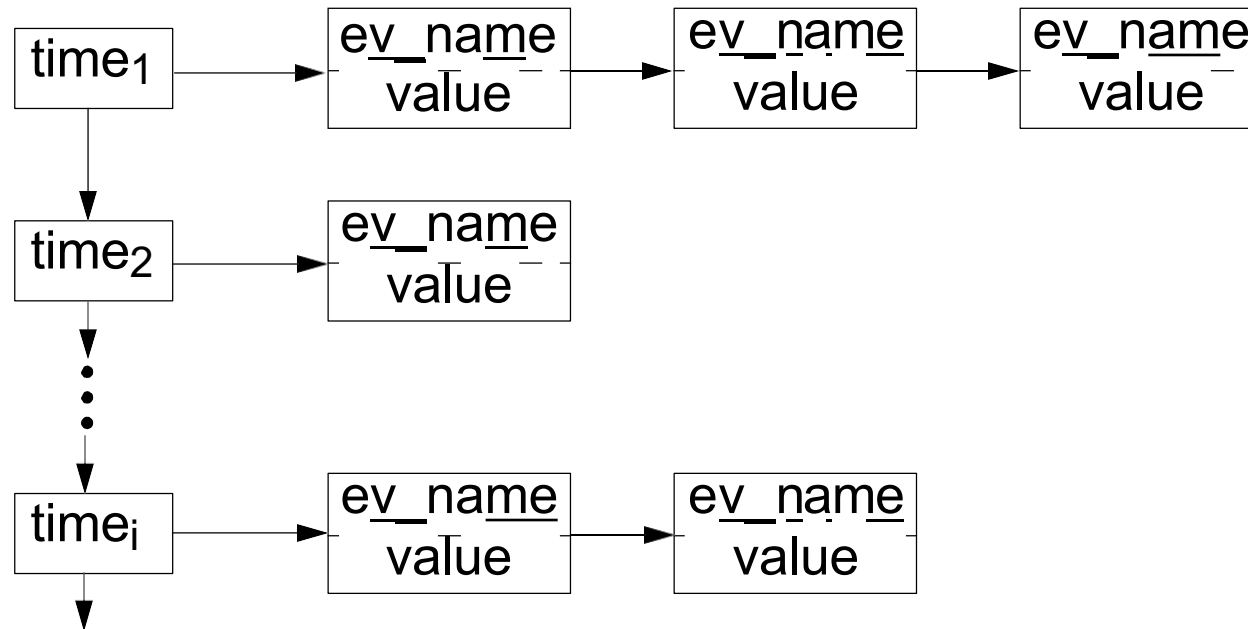

**Process P2**

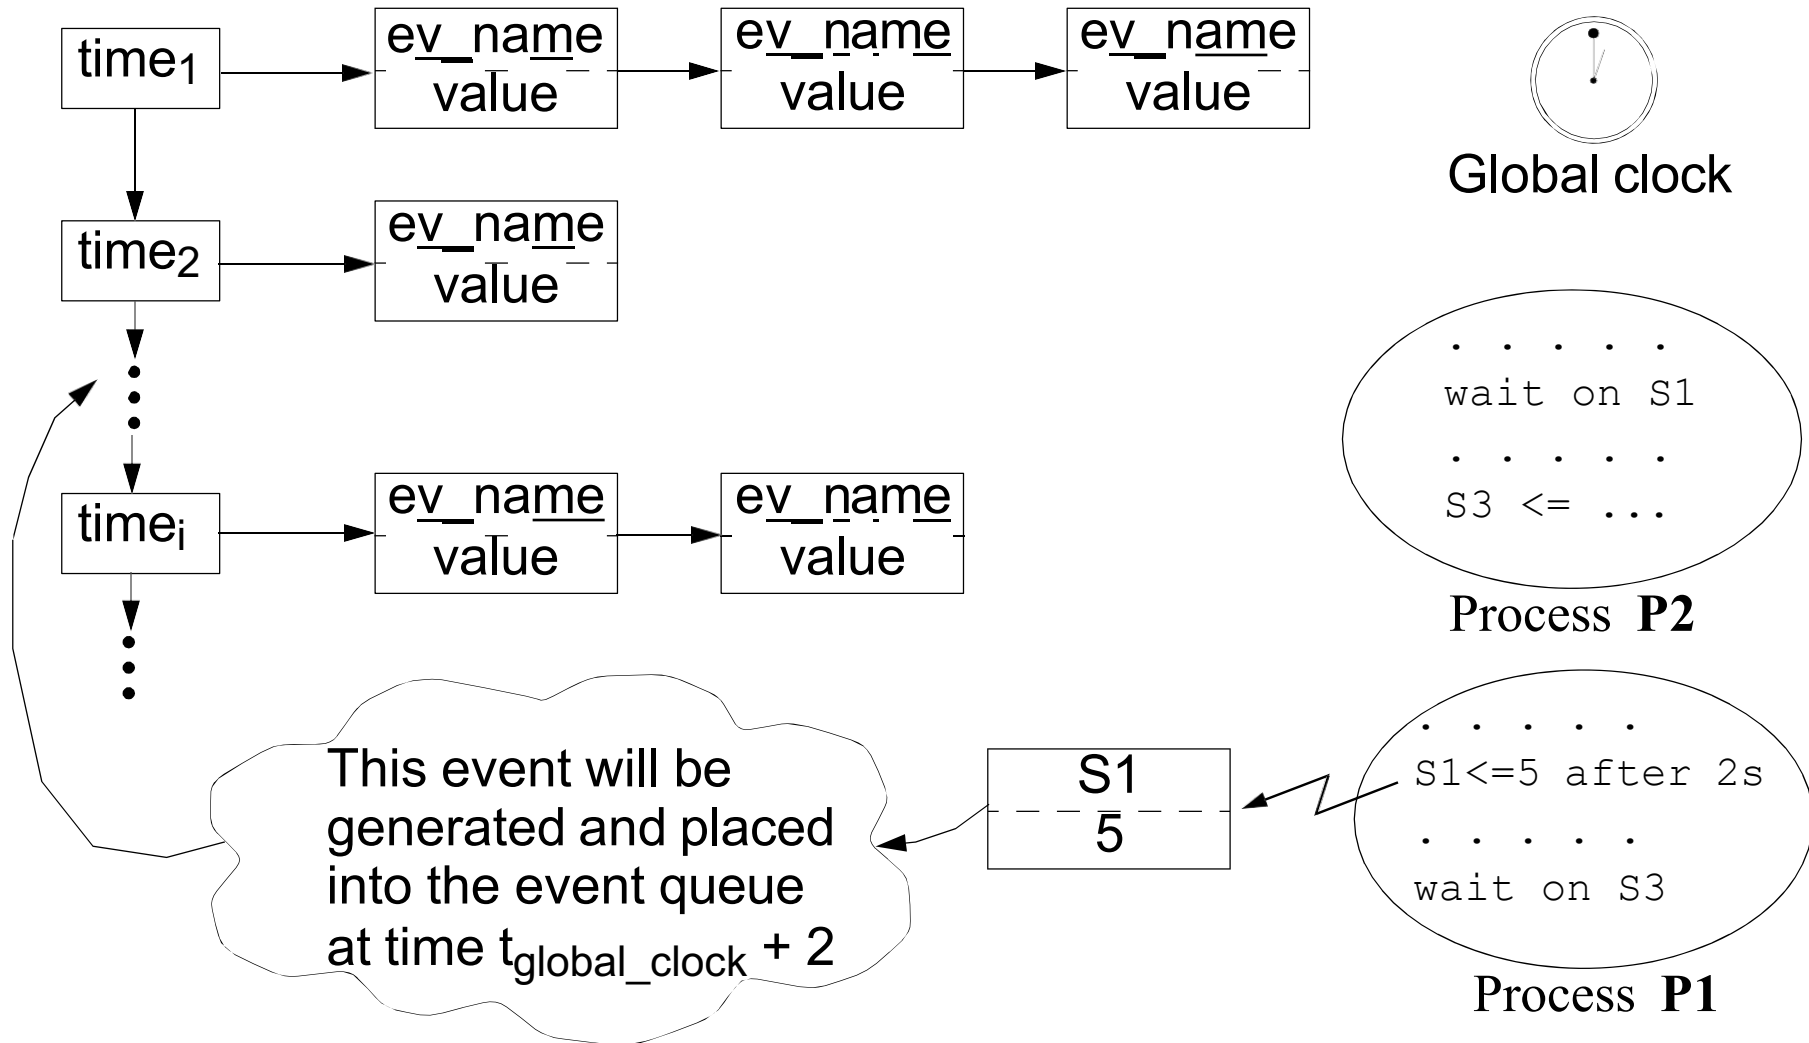

**Process P1**

# Discrete Event Simulator

# Discrete Event Simulation

- The discrete event model has been mainly used for system simulation.
  - Several languages have been developed for system modeling based on the discrete event model. Most well known:
    - VHDL, Verilog (both used for hardware modeling), **SystemC**
- Efficient way to simulate distributed systems.

In general, efficient for large systems with autonomous components, with relatively large idle times. Systems with non-regular, possibly long times between different activities.

Why is this the case?

Because DE simulation will only consider the particular times when a change in the system (an event) occurs. This is opposed to, for example, cycle-based models, where *all clock-ticks* are considered.

# Discrete Event Simulation

- **Event driven models are primarily employed for simulation.**
  - **Functional verification**
  - **Performance evaluation**
  
- **Both synthesis and formal verification are very complex with DE models.**
  - **The classical trade-off between expressive power and the possibility of formal reasoning and efficient synthesis.**

# An Example

# An Example

Process A

Process B

Process C

At time 10 Process A executes

# An Example

Process A

Process B

Process C

At time 10 Process A executes

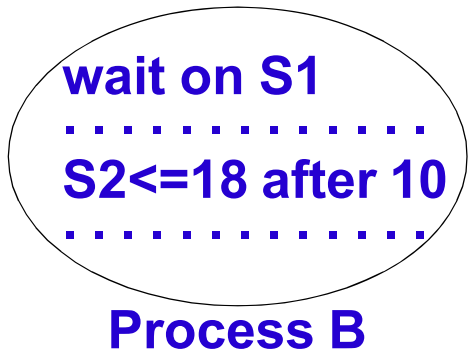

At time 15

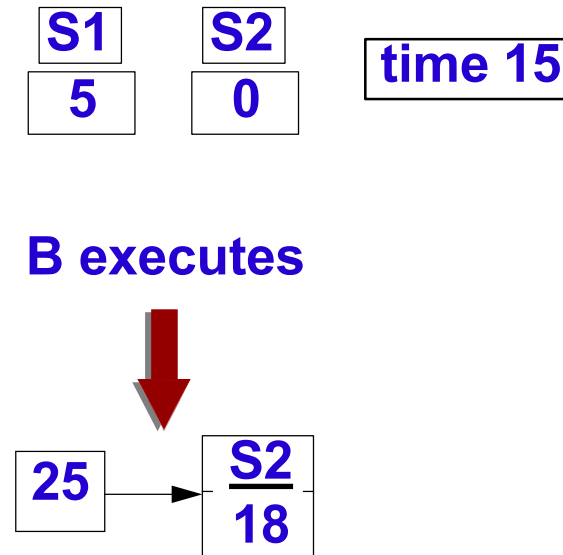

Processes B and C are ready to execute

C executes

At time 25

C executes

# Delta Delay/Delta Cycles

- A zero delay event will be registered at a time which is infinitesimally delayed relative to the current time.

*A delta delay* will be introduced on the event  $\Rightarrow$  the new event will be consumed in the following simulation cycle and not the current one.

# An Example

Process A

We have changed  
the example!  
No *after* clause!

A blue lightning-bolt shaped arrow points from the text to the 'after 10' part of Process B's code.
