- 4 2 2
- Use of Internet for content delivery is massive ...
- Content delivery can consume significant resources
  How to make scalable and efficient?
  - Consider content provider wanting to server catalogue of many contents

- Cost-efficient solution must scale with regards to both:
  - Request rate
  - Number of available contents

# Background: BitTorrent

### Single file download

- File split into many smaller chunks
- Downloaded from both seeds and downloaders
- Distribution paths are dynamically determined
  - Based on data availability

## Background: BitTorrent

Torrent file 
 ``announce-list" URLs

Trackers

- Register torrent file
- Maintain state information

#### Peers

- Obtain torrent file
- Announce
- Report status
- Peer exchange (PEX)

## Background: BitTorrent

Torrent file <sup>(1)</sup> • • •
 ``announce-list" URLs

Trackers

- Register torrent file
- Maintain state information

#### Peers

- Obtain torrent file
- Announce
- Report status
- Peer exchange (PEX)

#### Example 1: Download rate in BitTorrent

#### Download rate

Analysis and results presented in IPTPS 2009 and IEEE/ACM ToN

#### Example 1: Download rate in BitTorrent

#### Download rate

Analysis and results presented in IPTPS 2009 and IEEE/ACM ToN

  - Number of available contents

- Cost-efficient solution must scale with regards to both:
  - Request rate
  - Number of available contents

- Cost-efficient solution must scale with regards to both:
  - Request rate
  - Number of available contents

## Bundling (or torrent inflation)

Using some of the available upload bandwidth from currently downloading peers to "inflate" torrents for files that would otherwise require substantial server b/w

#### How to pick which files to bundle/inflate?

- Static bundling
  - Bundle at content creation
- Dynamic bundling
  - Adapt which files to bundle based on current popularities and conditions

Arrival rate

AGS UNI

Inflate lukewarm files (e..g, IEEE P2P 2012; Networking 2010)

### Proof of concept implementation

- Instead of looking at policy choices ...
- This paper presents the design and proof of concept implementation of a dynamic bundling system
  - Want to minimize changes to the BitTorrent protocol
  - Introduce concept of "super bundle" and "individual bundles"
  - Performance evaluation using simple baseline policies on PlanetLab

#### Four parts

- Tracker communication (bundle negotiation event and additional information)
- Bundling selection component at tracker
- Piece selection rule (as each peer have individual preferences and responsibilities)
- Disk writing algorithm

30

#### Example results: Steady-state

- Average download times
  - Again, naïve baseline policies
  - Still performance improvements ...
  - Big improvements for less popular files, at small cost at popular file

#### **Example results: Steady-state**

- 31
- **Download time distributions** 
  - Again, naïve baseline policies
  - Still performance improvements ...
    - Big improvements for less popular files, at small cost at popular file

32

#### Example results: Dynamic scenario

- Smaller download times
- Adapt to current conditions

33

### Contributions

- Presented the design of a dynamic bundling system, including a proof of concept implementation
  - Allow flexible adaptive policies to be implemented and tested with relatively small changes to the BitTorrent protocol
- Some example results are presented for naïve baseline policies
- Future work include
  - Design of a fully dynamic bundling system
  - PlanetLab testing of more advanced policies (as proposed/evaluated in other works; e.g., IFIP Networking 2010 and IEEE P2P 2012)
