1. Introduction

The cat (*Felis catus*, Linnaeus 1758) has lived around or with humans for at least 10,000 years, and is now one of the most popular pets of the world with more than 600 million individuals [1], [2]. Domestic cats have developed a more extensive, variable and complex vocal repertoire than most other members of the Carnivora, which may be explained by their social organisation, their nocturnal activity and the long period of association between mother and young [3]. Still, we know surprisingly little about the phonetic characteristics of these sounds, and about the interaction between cats and humans.

Members of the research project Melody in human–cat communication (Meowsic) investigate the prosodic characteristics of cat vocalisations as well as the communication between human and cat. The first step includes a categorisation of cat vocalisations. In the next step it will be investigated how humans perceive the vocal signals of domestic cats. This paper presents an outline of the project which has only recently started.

1.1. Previous studies

The phonetic characteristics of domestic cat vocalisations were first described by Moelk [4], and since then a number of acoustic characteristics of cat vocalisations have been described [5]–[12]. Based on previous descriptions as well as analysis of new recordings, an attempt was made to develop a comprehensive phonetic typology of domestic cat vocalisations, with phonetic definitions. Table 1 shows the number of vocalisation types and subtypes identified so far.

Table 1: The most common domestic cat vocalisation types and subtypes identified in this study.

Auditory as well as acoustic analyses have been used to identify and describe the different types. The descriptions include phonetic transcriptions, segmental and prosodic features, as well as typical contexts in which the vocalisations are used. These types are now used in the project for annotating and classifying cat vocalisations (see Figure 1 for an example waveform, spectrogram and fundamental frequency ($F_0$) contour of a vocalisation, and http://meowsic.info for additional video and audio examples.

\[ F_0 \] Hz and $F_0$ contour (bottom) of an example howl-growl.

Figure 1: Waveform (top), spectrogram (mid, bandwidth: 300 Hz) and $F_0$ contour (bottom) of an example howl-growl.

2. Vocalisation types

The following list is an overview of the vocalisation types we have identified so far along with their subtypes. Example phonetic transcriptions and typical contexts in which the vocalisation types are used are provided for each type.

1. Sounds produced with the mouth closed

   a. **Purring**: a low-pitched regular and probably nasalised sound produced during alternating (pulmonic) egressive and ingressive airstream: [wːɾːfːɾːhː…] or ; used when the cat is content, hungry, stressed, in pain, gives birth or is dying; probably signals “I do not pose a threat” or “Keep on doing what you are doing”.

   b. **trill (chirr, chirrup, grunt, murmur)**: a short and often soft, sometimes a bit harsh nasalised sound rolled on the tongue, i.e. a voiced trill: [mːɾːɾː], [mːɾːɾː]; used e.g. during friendly approach and greeting, and during play; grunts (murmurs) are usually more low-pitched, while trills or chirr(ups) are more high-pitched; sometimes cats combine a trill with a meow, producing the more complex vocalisation subtype trill-meow.

2. Sounds produced with an opening-closing mouth

   a. **meow (miaow) sounds**: Meows can be assertive, plaintive, friendly, bold, welcoming, attention soliciting, demanding, or complaining, sad or even silent. A meow can be varied almost endlessly, and there are several subtypes, including the following:
i. **mew**: a high-pitched meow with [i], [ɪ] or [e] quality: [mi], [wɪ] or [mɪu]; kittens may use it to solicit attention from their mother, and adult cats may use it when they are sad or in distress or when they signal submissiveness

ii. **squeak**: raspy, nasal, high-pitched and often short mew-like call, sometimes with an [e] vowel quality: [we], [me] or [ru], sometimes not ending with a closing mouth; often used in friendly requests

iii. **moan**: with [o] or [u] vowels: [moau] or [maeu]; often used when sad or demanding

iv. **meow (miaow)**: a combination of vowels resulting in the characteristic [ia] sound: [miau], [rau] or [waau]; often used in cat-human communication to solicit food or get past an obstacle (e.g. a closed door or window); adult cats mainly meow to humans, and seldom to other cats, so adult meow could be a post-domestication extension of mewing by kittens

b. **trill-meow (murmur-meow)**: combination of a trill (murmur) and a meow: [mhriau], [mhrr-au] or [whrrau]; used in the same contexts as the meow

c. **howl (yowl, moan, anger wall)**: long and often repeated sequences of extended vocalic sounds – often with [i], [ɪ], [j], [y], [ai], [ei], [aw], [oi], [oa] – usually produced by gradually opening the mouth wider and closing it again; used in threatening situations, and often merged or combined with growls in long sequences with slowly varying F0 and intensity: [gr:awjao:] or [gr:awjao:]

d. **matting cry (matting call)**: long sequences of meow-like sounds, sometimes similar to the cries of human infants; often used in spring during the mating season: [waːuw], [ɛːwːuː], [mhːwaːuːiː] or [kwːwːuːaːu]

3. Sounds produced with an open tense mouth are often associated with either offensive or defensive aggression, but also with prey-directed vocalisations

a. **growl (snarl)**: long guttural, harsh, regularly and rapidly pulse-modulated, low-pitched sounds produced during a slow steady exhalation, often with the lips curled up and exposed teeth [gr:], with a vocalic [i] or rothic [a], occasionally beginning with an [m]; used to signal danger or to warn or scare off an opponent, and often interwoven or merged with howls and hisses

b. **hiss and spit** (the more intense variation): agonistic (aggressive and defensive) sounds produced with the mouth wide open and the teeth exposed, sounding a bit like long exhalations: [h:], [b:], [v:], [f:] or [s:]; often an involuntary reaction to being surprised by an (apparent) enemy; the cat changes position with the stare and breath is being forced rapidly through the slightly open mouth before stopping suddenly; the spit sounds similar to a hiss, but may sometimes begin with a stop – often a t-like sound: [ʃː], [lː], [kː]

c. **snarl (scream, cry, pain shriek)**: loud, harsh and high-pitched vocalic sounds, often with [a], [e], [æ], [ə] or [ro] vowels: [æːʊ]; often produced just before or during active fighting, or when in pain

d. **chirp and chatter** (prey-directed sounds): a hunting instinct where cats copy the calls of their prey, e.g. when a bird or insect catches their attention (by making a sound) and the cat becomes riveted to the prey, and starts to chirp, tweet and chatter:

i. **chatter** (teeth chattering): unvoiced very quick stuttering or clicking sequences of sounds with the jaws juddering, [k k k k k k]

ii. **chirp**: voiced short calls said to be mimicking a bird or rodent chirp, sound similar to a high-pitched phone ring, tone often rises near the end, [ʔːɾ] or reiterated [ʔɾeɾeɾeː...]

iii. **tweet and tweedle**: tweets are soft weak chirps, often without any clear initial [ʔ] and with varying vowel qualities: [wi] or [frica]: tweedles are prolonged chirps or tweets with some voice modulation, like tremor or quaver: [ʔəɾɵɾəɾ]

Previous pilot studies have revealed that experienced human listeners are fairly good at recognizing the vocal signals of domestic cats [13, 14]. In future studies we intend to investigate this further.

Appropriate Voices for Artefacts: Some Key Insights

Roger K. Moore

Abstract

The 2011 release of Siri hailed the beginning of a sustained period of impressive advances in the capability and availability of spoken language technology. Subsequent years saw the appearance of competitors such as Google Now, swiftly followed by consumer products such as Amazon Echo. These devices are seen as the first steps towards more advanced ‘conversational’ artefacts (especially robots). However, evidence suggests that the usage of such voice-enabled devices is surprisingly low, perhaps due to noise in the environment, privacy concerns or manual alternatives. Another possible contributing factor is that the ubiquitous deployment of inappropriate humanlike voices for non-living artefacts might deceive users into overestimating their capabilities, thereby creating a conflict of expectations that ultimately leads to a breakdown in communications. This paper highlights the benefits of providing an appropriate voice for a given artefact based on three separate studies. Results are presented that demonstrate the positive impact of a non-human voice and illustrate how ‘appropriateness’ might be measured objectively. Finally, a worked-example is presented of implementing an appropriate voice for the MiRo biomimetic robot. It is concluded that these insights could be important for the design of future generations of voice-enabled artefacts.

Index Terms: appropriate voices, robot voices, speaking artefacts

1. Introduction

After more than 40 years of research into spoken language processing, the 2011 release of Siri - Apple’s voice-based ‘personal assistant’ for the iPhone - represented a significant milestone in bringing speech technology to the attention of the general public. It also hailed the beginning of a sustained period of impressive advances in the capabilities of the underlying speech technologies with dramatic improvements in the accuracy of ‘automatic speech recognition’ (ASR) and the quality of ‘text-to-speech synthesis’ (TTS). Subsequent years saw the appearance of smartphone-based competitors to Siri such as Google Now and Microsoft’s Cortana, swiftly followed by voice-enabled consumer products such as Amazon Echo and Google Home. These latter devices are seen as the first stepping stones towards more advanced ‘conversational’ artefacts in the future, in particular ‘autonomous social agents’ (such as robots) - see Fig. 1.

Notwithstanding the popularity of contemporary voice-enabled devices, it appears that actual usage is surprisingly low (see Fig. 2) [1]. Indeed, it seems that voice interfaces maintain their notoriety for “fostering frustration and failure” [2].

There are a number of potential explanations for this lack of genuine take-up: e.g. noise in the environment, privacy concerns or manual alternatives. However, it is argued here that another contributing factor could be the ubiquitous deployment of humanlike voices for artefacts that are clearly not human. Not only is this true of mainstream speech-based systems such as Siri and Echo, but it is also typical to find that robot research laboratories have equipped their devices with off-the-shelf humanlike speech synthesis on the basis that it’s “natural” that people should wish to interact with a robot using ‘normal’ speech. The reality is that, when faced with such artefacts, users tend to be deceived into overestimating their capabilities, creating a conflict of expectations that ultimately leads to a breakdown in communications (much like the famous ‘uncanny valley’ in robotics [3, 4, 5]) - the opposite of what was intended.

In practice, it would be relatively easy to manage users’ expectations by giving artefacts an appropriate non-human, rather than humanlike, voice. In principle, such an approach would avoid the pitfalls of the ‘uncanny valley’ by aligning an artefact’s visual, vocal and behavioural affordances [6, 7, 8], and would create a more ‘habitable’ interface in line with the ideas expressed in Bruce Balentine’s seminal book on the usability of...
