Design research is alive and well, and living in an increasing number of places. I find encouraging evidence for this in the growth of research-based journals in the design world over the last ten to fifteen years. For example, Design Studies was launched in 1979; Design Issues first appeared in 1984; the Journal of Design History in 1988; Research in Engineering Design in 1989; and Languages of Design in 1992. These are not the only ones; and there have been others, of course, in other languages, such as Temes de Disseny (Catalan and Spanish), 1986; Revue Sciences et Techniques de la Conception (French), 1992; FormDiskurs (German), 1996.

There has also been a lot of design-oriented research reported in a wide range of journals concerned with artificial intelligence, human-computer interaction, and so on. Compared with the academic design scene in the 1970s, we now have a rich culture in which to grow our design research seedlings.

Each of these design research journals draws upon scholarship paradigms from the sciences or the arts. A history-based journal such as Journal of Design History clearly draws upon paradigms of scholarship in the arts and humanities, and an engineering-based journal such as Research in Engineering Design leans heavily on the research paradigm of the natural sciences. But the important thing is that collectively we have the possibility of adding to these other paradigms and of developing our own design research culture.

At the Design: Science: Method conference of the Design Research Society, in 1980, Bruce Archer gave a general definition of research, which is that "Research is systematic inquiry, the goal of which is knowledge." Our concern in design research has to be the development, articulation and communication of design knowledge. Our axiom has to be that there are forms of knowledge peculiar to the awareness and ability of a designer, just as the other intellectual cultures in the sciences and the arts concentrate on the forms of knowledge peculiar to the scientist or the artist.

Where do we look for this knowledge? I believe that it has three sources: people, processes and products.

Design knowledge resides firstly in people: in designers especially, but also in everyone to some extent. Designing is a natural human ability. Other animals do not do it, and machines (so far) do not do it. We often overlook the fact that people are naturally very good at design. We should not underplay our abilities as designers, many of the most valued achievements of humankind are works of
design, including anonymous, vernacular design as well as the “high design” of professionals.

One immediate subject of design research, therefore, is the investigation of this human ability—of how people design. This suggests, for example, empirical studies of designer behavior, but it also includes theoretical deliberation and reflection on the nature of design ability. It also relates strongly to considerations of how people learn to design, to studies of the development of design ability in individuals and how that development might best be nurtured in design education.

Design knowledge resides secondly in its processes: in the tactics and strategies of designing. A major area of design research is methodology: the study of the processes of design, and the development and application of techniques which aid the designer. Much of this research revolves around the study of modeling for design purposes. Traditional models are the sketches and drawings of proposed design solutions, which in contemporary terms now extend to “virtual reality” models. The use of computers has stimulated a wealth of research into design processes; so has the development of new practices in industry such as concurrent engineering.

Thirdly, we cannot forget that design knowledge resides in products themselves: in the forms and materials and finishes which embody design attributes. Much everyday design work entails the use of precedents or previous exemplars—not because of laziness by the designer but because the exemplars actually contain knowledge of what the product should be. This is certainly true in craft-based design: traditional crafts are based on the knowledge implicit within the object itself of how best to shape, make, and use it. This is why craft-made products are usually copied very literally from one example to the next, from one generation to the next.

As with the design knowledge that resides in people, we would be foolish to disregard or overlook this informal product knowledge simply because it has not been made explicit yet; that is a task for design research. So too, is the development of more formal knowledge of shape and configuration, the theoretical studies of design morphology. These may be concerned as much with the semantics as with the syntax of form, or may be concerned with prosaic matters of efficiency and economy, or with relationships between form and context—whether ergonomics or environment.

My own taxonomy of the field of design research would therefore fall into three main categories, based on people, process and products:

- design epistemology
  —study of designerly ways of knowing
- design praxiology
  —study of the practices and processes of design
- design phenomenology
  —study of the form and configuration of artifacts.
What clearly has been happening in the field of design research in the last decade or so is that there has been a growing awareness of the intrinsic strengths and appropriateness of design thinking within its own context. There has been a growing acceptance of design on its own terms, a growing acknowledgment and articulation of design as a discipline in its own right. We have come to realize that we do not have to turn design into an imitation of science, nor do we have to treat design as a mysterious, ineffable art. We recognize that design has its own distinct intellectual culture; its own designerly “things to know, ways of knowing them, and ways of finding out about them.”

This view of design as a distinct culture is also embodied in attempts to break away from C. P. Snow’s “two cultures” view of Western intellectual tradition, the two cultures of the Arts and Sciences. It has to be recognized that there is at least one other culture, which we might regard as the culture of Design, which can be articulated in comparison with the other two.

For instance, the “things to know,” the respective fields of knowledge, are the natural world for science, human experience for art, and the artificial world for design; the “ways of knowing,” the values of science are rationality and objectivity, those of art are reflection and subjectivity, and those of design are imagination and practicality. Similarly, the “ways of finding out,” the intellectual skills, can be differentiated: those of science are experiment and analysis, those of art are criticism and evaluation, and those of design are modeling and synthesis.

The above categorizations may be rather simple, but many researchers in the design world have been realizing that design does indeed have its own strong and appropriate intellectual culture, and that we must avoid totally swamping our research with different cultures imported either from science or art. This does not mean that we completely ignore these other cultures. On the contrary, they have much stronger histories of inquiry, scholarship, and research than we have in design. We need to draw upon those histories and traditions where appropriate, while building our own intellectual culture, acceptable and defensible in the world on its own terms. We have to be able to demonstrate that standards of rigor in our intellectual culture at least match those of the others.

In The Sciences of the Artificial, Herbert Simon went so far as to say that “The proper study of mankind is the science of design.” (Of course, the quotation is a corruption from Pope’s original version, that “the proper study of mankind is man.”) What Simon was suggesting was that the study of design could be a fundamental, interdisciplinary study accessible to all those involved in the creative activity of making the artificial world (which includes all mankind). For example, Simon wrote that “Few engineers and composers . . . can carry on a mutually rewarding conversation about the content of each other’s professional work. What I am

---

suggesting is that they can carry on such a conversation about design, can begin to perceive the common creative activity in which they are both engaged, can begin to share their experiences of the creative, professional design process."

This, it seems to me, is the challenge for design research, to help construct a way of conversing about design that is at the same time both interdisciplinary and disciplined. We do not want conversations that fail to connect across disciplines, that fail to reach common understanding, and that fail to create new knowledge and perceptions of design. It is the paradoxical task of creating an interdisciplinary discipline.

For some leading examples of this developing conversation, we might turn to the series of papers which, in recent years, have won the annual Design Studies Award for the best paper published in that journal. These examples have originated in design research conducted in different domains and with different methodologies, but each individual contribution has had something to say to members of the wider design research community.

The Award was first instituted in 1987, and a selection of the winners includes:

Donald Schön¹ (Urban Planning, MIT, USA) Designing: Rules, Types and Worlds Analysis of design protocols to identify patterns of reasoning based on rules derived from type-concepts.

Jacob Burr and Myrup Andreason² (Engineering, Lyngby University, Denmark) Design Models in Mechatronic Product Development Analysis of the properties of design models, leading to proposals for models appropriate to mechatronic product design.

Frances Downing³ (Architecture, Texas A&M University, USA) Conversations in Imagery Study of the role of memory (mental imagery of memorable places) in the architectural design process.

Robin Roy⁴ (Design & Innovation, The Open University, UK) Case Studies of Creativity in Innovative Product Development Studies of creative individual designers to gain insight into the creative process and innovative product development.

Gabriela Goldschmidt⁵ (Architecture, Technion, Haifa, Israel) The Designer as a Team of One Comparative protocol analyses of an individual designer and a small team tackling the same design problem.

Terry Purcell and John Gero⁶ (Design Science, Sydney University, Australia) Design and Other Types of Fixation Experimental studies of problem solving in design, aimed at understanding the causes and effects of fixation.

Jars-Erik Janlert and Erik Stolterman⁷ (Computing and Informatics, Umea University, Sweden) The Character of Things A consideration of how things (hardware and software), as well as people, can have a “character.”

What these examples of “best practice” in design research have in common include the following characteristics.
The research is:
*Purpose*, based on identification of an issue or problem worthy and capable of investigation.
*Inquisitive*, seeking to acquire new knowledge.
*Informed*, conducted from an awareness of previous, related research.
*Methodical*, planned and carried out in a disciplined manner.
*Communicable*, generating and reporting results which are testable and accessible by others.

These characteristics are, of course, normal features of good research in any discipline. I do not think that such normal, academic criteria inhibit or preclude research that is “designerly” in its origins and intentions. However, they would exclude works of so-called research that fail to communicate, and which are undisciplined or ill-informed.

I think also that we should draw a distinction between works of practice and works of research. I do not see how normal works of practice can be regarded as works of research. The whole point of doing research is to extract reliable knowledge from either the natural or artificial world, and to make that knowledge available to others in re-usable form. This does not mean that works of design practice must be wholly excluded from design research, but it does mean that, to qualify as research, there must be reflection by the practitioner on the work, and communication of some re-usable results from that reflection.

The design fields covered in the selected papers, above, have included architectural design, engineering design, industrial design and software design, and the methods of inquiry underlying the research have ranged from philosophical analysis, through case studies and interviews, to protocol studies. They are examples drawn from an ongoing research “conversation” about design which is being shared by members of widely differing professions and disciplines. They draw upon the research paradigms and methods of both the arts and the sciences, but they also contribute to the emerging paradigms and methods of design research.

One of the dangers in this new field of design research is that researchers from other, non-design, disciplines will import methods and approaches that are inappropriate to developing the understanding of design. Researchers from psychology or computer science, for example, have tended to assume that there is “nothing special” about design as an activity for investigation. However, developments such as artificial intelligence and other computer modeling in design have perhaps served mainly to demonstrate the high-level cognitive ability of designers, and how much more research is needed to understand it. Better progress seems to be made by designer-researchers, and for this reason the recent European series of workshops and symposia on descriptive model-
ing of design by Cross et al., Akin et al., Frankenburger at al.,
featuring a younger generation of designer-researchers, has been extremely useful in developing the methodology of inquiry in
design research. As design grows as a discipline with its own
research base, so we can hope that there will be a growth in the
number of emerging designer-researchers.

Another of the dangers is that researchers adhere to under-
lying paradigms of which they are only vaguely aware. We need to
develop this intellectual awareness within our community. A good
example here is the work of Kees Doorest, in making an explicit
analysis and comparison of the paradigms underlying the approach
of Herbert Simon, on the one hand, and Donald Schön on the other.
These two scholars have been the most influential in our field,
representing positivist and constructivist philosophies, respectively.
Simon’s positivism leads to a view of design as “rational problem
solving,” and Schön’s leads to a view of design as “reflective prac-
tice.” These two might appear to be in conflict, but Dross’s use of
the two paradigms in analyzing design activity leads him to the
view that the different paradigms have complementary strengths
for gaining an overview of the whole range of activities in design.

We are still building the appropriate paradigm for design
research. My personal “touchstone” theory for this paradigm is that
there are “designerly ways of knowing:” many of the examples of
design research I have referred to are contributions to building our
understanding of this concept of particular, designerly ability. I
believe that building such a paradigm will be helpful, in the long
run, to design practice and design education. We still know rela-
tively little about the mystery of design ability, and that limits our
“proper study of mankind.” This is the goal for design research.
